Dr. Maclean's career as a writer was a long and varied one. He communicated to the medical press at home and in India a great variety of articles on the medical and surgical questions of the day and on questions affecting the constitution, status, and work of the public medical services, many of which have appeared from time to time in our columns. He contributed nearly all the articles on tropical medicine to the great work of Dr. Russell Reynolds, the "System of Medicine," and the articles on tropical fevers to the successive editions of Sir Richard Quain's "Dictionary of Medicine." He was also the author of "Diseases of Tropical Climates," 1886, a work which was long the text-book used in the Army Medical School and the foremost authority on these complaints. Among his other contributions to medical literature were the following papers:—The Influence of the Knapsack and Accoutrements on the Health of the Infantry Soldier, *Journal of the Royal United Service Institution*, vol. viii., 1865; Sanitary Precautions to be observed in the Moving and Camping of Troops in Tropical Regions, ibid., 1874; Prevalance of Enteric Fever among Young Soldiers in India, International Medical Congress, 1881; Remarks on the Cases of Enteric Fever admitted from Egypt into the Medical Division R.V. Hospital, Army Medical Report, vol. xxiii., 1882; and the Fever of Malta and Gibraltar, *Practitioner*, vol. xxxiv., 1885. As a writer we cannot help feeling that his career of usefulness might have been even more extended had not his desire to publish the lectures delivered in the Army Medical School from time to time, chiefly for the benefit of the officers of the services scattered over the tropics, been interfered with by the Secretary of State for War. It will be remembered that the lecture which he published in THE LANCET on the very disgraceful conduct of affairs during the epidemic of yellow fever at Bermuda in the year 1863 caused a great storm to burst about his head, and that although the War Minister, after inspecting the lecture, could find no fault with it, yet he was pleased to direct that in future all lectures delivered at the school should be submitted to him before publication—an order which acted as a permanent check on Dr. Maclean's intended policy, for, as he writes in his charming work, "Memories of a Long Life," "I am so constituted that I cannot publish under a censorship, however mild, judicious, or even generous."

Hitherto we have sketched, as far as our space will permit, a record of Dr. Maclean's life-work—a record of a man's labour ably carried out, of the engrossing work of an able physician; but what of the man himself? From the foundation of the Army Medical School to the day he delivered his last lecture no less than 1476 officers received instruction from him, and we know we are right in saying that to one and all of the survivors the report of his death has carried a sense of personal loss. We publish a reproduction of the picture by Mr. W. R Symonds now adorning the walls of the ante-room at the Officers' Mess, Netley, which was subscribed for by the officers of the Sister Services. It is a faithful portrait of Dr. Maclean's truly noble countenance and frame. In stature he was tall, with a commanding presence, and a fine head well poised on broad shoulders. His manner had a charm which at once set those around him at their ease, and all those associated with him were quickly convinced of the absolute sincerity of all he uttered. Frankness, we should say, was his great characteristic—his voice, the grip of his hand, the glance of his eye, all made one feel that he was a trusty and trusting friend; and, withal, he was strong, mentally, physically, morally—a man upon whom many others leant and gathered strength from the association. As a lecturer and public speaker he had few equals, and as he spoke so he wrote. To the circle to whom he gave copies of his latest literary effort, his "Memories of a Long Life," what pleasure has been conveyed, for as they read the details of a life well spent they can almost fancy they are listening to his well-loved tones. In his last lecture delivered at the Army Medical School, in which he passed in review what had been done for the army by the Netley teaching, in speaking of his own special work he said: "Unless treatment had to a large extent kept pace with sanitation the results we contemplate with so much satisfaction could not have been obtained. If this is so—and the fact appears to me undeniable—we may claim for this school that the money spent on it has not been spent in vain, and that the wisdom of those who founded it has been justified."

All through his life Dr. Maclean was a keen sportsman,

Digitized by Google

After his second return from India he never missed an annual visit to Hythe Hall every 12th of August, always remaining there until obliged to return to his professional duties on Oct. 1st. This routine never varied until the death of his friend Mr. Hugh Maclean in 1885. For the last years of his life Dr. Maclean was a great sufferer from phosphatic stone and enlargement of the prostate, and we believe underwent as many as eight crushing operations performed by Mr. Reginald Harrison.

Happy in his public career Dr. Maclean was no less so in his private life. Returning to Hyderabad on Jan. 30th, 1845, soon after the death of his well-loved brother, Roderick Norman Maclean, who had served as aide-de-camp to Lord Ellenborough when Governor-General of India, he there met Louisa, daughter of John Maclean of Branley, in Inverness, a niece of his brother-in-law, General Duncan Macpherson. An engagement soon followed and he was married on Sept. 9th, 1845, from the house of his friend Dr. Alexander Walker of the Bombay Army. The issue of the marriage was three sons and two daughters—two of the sons are now planters in Ceylon, while one son is a member of the Mexican Legation; of his two daughters, the elder married Mr. John Macpherson of the Inner Temple, the younger is the wife of Colonel Stevens of the Royal Artillery. Mrs. Maclean survives him, and to her all those who knew her husband are extending the sympathy which words are inadequate to express.

ALEXANDER SIMPSON, M.A. ST. AND., M.D., B.SC. EDIN.

DR. ALEXANDER SIMPSON, medical officer of health of the city of Perth, died at his residence there on Oct. 23rd in consequence of injuries sustained by falling downstairs on Oct. 21st. Dr. Simpson took the degree of M.A. at St. Andrews University in 1871, studied medicine at Edinburgh, and graduated in the university there as M.B. and C.M. in 1878. After spending a short time as assistant to an uncle who was in practice in London he settled in Perth and was appointed medical officer of health of the city and police surgeon on the resignation of these offices by Dr. Buist about seventeen years ago. In 1885 he took the degree of M.D. and in 1892 that of Bachelor of Science in Public Health. Dr. Simpson was deeply interested in the work of the St. Andrew's Ambulance Association, conducting large classes to which the usual course of instruction in first aid was given. He has left a widow and four young children.

EDWARD DEANE MACDERMOT, M.A., M.D. T.C.D.

DR. EDWARD DEANE MACDERMOT, who was one of the oldest medical practitioners of Bath, died at his residence, The Circus, on Nov. 9th, after an illness of only two weeks' duration. Dr. MacDermot, who was a member of an old Irish family, received his education at Trinity College, Dublin, and graduated M.A. and M.D. in 1848. Shortly afterwards he went to Bath as an assistant to a medical man at Bathwick, and subsequently started practice in Brook-street, removing from there to The Circus. The deceased was highly esteemed and popular in Bath and possessed a considerable amount of Irish wit and humour. Dr. MacDermot was twice married, his second wife being Lady Wade, the widow of Sir Claude Wade, a distinguished diplomatist and soldier, by whom he leaves a son. The funeral took place at Ardcarne near Boyle, the family burial place in the west of Ireland.

ALLEGATIONS AGAINST A MEDICAL OFFICER.—At the meeting of the Newport Board of Guardians held on Nov. 5th the report was read of Mr. Bircham, of the Local Government Board, who has recently held an inquiry in connexion with the allegations against the medical officer of the workhouse (Dr. T. G. Macormack). This completely exonerated that gentleman from the charges of neglecting the patients at the infirmary, Mr. Bircham remarking that he found the patients were exceedingly well treated by Dr. Macormack and the nursing staff. The report added that there was considerable friction between the infirmary branch of the workhouse and the administrative portion, which it was hoped would have the special attention of the guardians.

"Audi alteram partem."

"OBSERVATIONS ON AN INFECTIOUS DISEASE IN LASCARS HAVING CLOSE RELATIONS WITH VARIOLA AND VARICELLA."

To the Editors of THE LANCET.

SIRS,—I have read with much interest the paper bearing the above title by Dr. Thomson and Dr. Brownlee of Glasgow in your issue of Oct. 22nd last. Therein they refer at some length to a paper of mine read before the Epidemiological Society of London in 1866, on "Epidemic Varioloid Varicella in Jamaica," in which I described an outbreak of a peculiar form of disease which neither before nor since have I met with. I gave it the name I did for want of a better, and it was not until I read the paper of Dr. Thomson and Dr. Brownlee that I appreciated the possibility that I had described a disease which had hitherto not been classified. As pointed out by them, the two epidemics in all their important characteristics are nearly identical, and any slight differences may be accounted for by the fact that I had at least 115 cases and they only 16, the larger number of cases affording a greater variety in the clinical manifestations of the disease. After the lapse of thirty-five years I fear I cannot depend upon my memory to afford information on the points whereon Dr. Thomson and Dr. Brownlee indicate that my account is deficient.

To clear up two questions involving uncertainty referred to by Dr. Thomson and Dr. Brownlee, I may, however, state that my epidemic was certainly not varicella modified by *racial* differences. I attended persons of all colours with it—not only blacks, but whites, and many of the mixed races. Nor was it due to *climatic* differences. In thirty-four years' practice in the tropics I have observed many epidemics of both variola and varicella, the result of my experience being that these diseases present precisely the same symptoms and are as clear, distinct, and easy of diagnosis as in England, the only difference being that in the coloured races the rosy areola surrounding the eruption is not so well marked. Neither, in my opinion, was the disease variola, of which I have seen several epidemics. Many months after this anomalous epidemic one of genuine small-pox broke out and I attended a large number of cases, none of which presented the slightest approximation to the one that I described in my paper. Appended to my paper in the Transactions of the Epidemiological Society of London is a note by my partner, the late Dr. Bowerbank—an extremely able physician of long experience—who saw a large number of these cases with me. It is as follows:—

"March 10th, 1863.—We are at present suffering from a severe influenza and also from a most peculiar epidemic of varicella, I suppose. To me it looks much more like varioloid or modified small-pox; most of the vesicles suppurate and in some cases are distinctly umbilicated and are sometimes confluent. I never saw varicella like it before."

"Jan. 25th, 1864.—We have had among us a peculiar varioloid affection, something like purulent chicken-pox. Many of the pustules, however, exactly resemble true variola. The disease spread through the penitentiary and reformatory schools, 40 or 50 having it at one time. Since then it has appeared from time to time in a home and gone through the family, but it did not appear to me to take hold of a district."

For further information regarding this epidemic I would refer to my original paper. But I may here state that it occurred among old and young, vaccinated as well as unvaccinated, and also in some who had had severe attacks and were deeply pitted by antecedent small-pox. The constitutional symptoms were extremely mild and none of the patients died. It would be interesting to learn whether practitioners in the tropics or among those recently arrived therefrom have met with similar cases or whether possibly they have been noticed in this country. I certainly consider that it is highly desirable that this subject should receive further consideration, as thereby some anomalous circumstances regarding the relations between small-pox and vaccination might be cleared up. At present I feel

Digitized by Google

strongly inclined to adopt the suggestion of Dr. Thomson and Dr. Brownlee that "the disease is neither variola nor varicella but is probably a third disease of a specific character presenting resemblances to both, while at the same time it possesses certain features which entitle it to be placed by itself as a specific entity, and having the same relation to both the diseases mentioned as exists between the more familiar forms of small-pox and chicken-pox."

I am, Sirs, yours faithfully,

IZETT ANDERSON, M.D. Edin.

Eastbourne, Nov. 14th, 1898.

"VITALITY."

To the Editors of THE LANCET.

SIRS,—I regret that I am unable to accompany some of your correspondents in the tremendous journeys they seem to contemplate, nor do I think it would be profitable just now to discuss what happened many millions of years ago. Although unquestionably our sun is "with surpassing glory crowned," there is no evidence of his having created, constructed, or built anything, nor can I believe that the sun with all his mighty energy can form a muscle, give origin to a weed, or build a wigwam. The doctrines favoured by my old friend Dr. Hooper and by Dr. Rowe concerning the origin of life in the remote past may be discussed when the general nature of *existing life* has been more fully considered.

I have long ago given my reasons for my belief in *vital power*, and have ventured to appeal to members of the profession to consider the conclusions arrived at as well as my microscopical observations extending over many years upon which they are founded. The main question applies to life *as it is*, as we know it here—life always followed by death—the nature of living matter, from that which exists in the lowest and simplest of living organisms, to that concerned in the formation and action of the so-called "cell" of our brain; and I beg my friends to freely criticise my contentions; to expose my errors or explain away my facts, in order that I may, perhaps in a modified way, further extend the account of my investigations in hope of being able to help in establishing conclusions of great interest and consequence, with reference to one of the most important scientific problems ever presented for solution—*the nature of vital power now* in active operation throughout the whole living world in which we find ourselves the highest of all living forms.

Now, one most important characteristic of all life is *growth*—the growth known *only in connexion with life*. It has been said, and it is widely believed, that growth also occurs in non-living matter and that the process I hold to be vital only, is but a form of aggregation of material particles. This doctrine I can only meet with a direct negative. The formation and increase of every tissue—every structure of every living organism that I have been able to study—does not take place according to any such process, and is absolutely dependent upon purely vital phenomena in each case. The facts of microscopical investigations extending over a long period have convinced me that there is no "community of nature" between *growth* as it occurs in everything that lives, and *inorganic growth*, as has long been taught by Mr. Herbert Spencer, and is re-asserted in his new edition just published and dated August, 1898. I venture to maintain that living and non-living matter belong to *absolutely different categories;* and that there is no analogy whatever between aggregation and accretion—and *growth* as it occurs in all living. The statements in the first paragraph of the chapter on Growth, § 43, p. 135, seem to me to be contrary to evidence, opposed to reason, and incompatible with *broad facts of living nature*, as well as with the results of minute investigation.

"Crystals grow" (Herbert Spencer). If the solution containing the crystallisable substance passed through the *outer part of the crystal* and crystallised within: *if* the new matter somehow reached the central part of the crystal: *if* the outer layers of the crystal consisted of the matter *first* deposited from the solution: *if* the crystal increased in size by deposition *from within* so that the superficial layers were pushed outwards as the crystals increased in dimensions—in short, *if* the deposition of crystallisable matter from its solution occurred in a direction *the very opposite of that* in which it does occur—the existence of some slight analogy between *growth* as it takes place in the "cell" of a living organism and the so-called *growth* of the crystal might be conjecturally assumed.

If the "fungus-like accumulation of carbon" upon the wick of an unsnuffed candle was increased by the last-formed portion of the carbon being somehow carried inwards through the outer layer towards the wick, so as to push out the layer first deposited, it might be said that the order of deposition was in the same direction and situation as occurs in the so-called cell-wall as in certain cases it is thickened.

If the deposition of sediment occurred beneath the stratum just deposited instead of *upon* it, the process might be roughly compared with *living growth*. *If* "celestial bodies" increased by deposition *from within*, and the last matter added reached the nucleus or central part, their increase might by some authorities be compared with growth "in its widest acceptation" (Herbert Spencer).

Evolution surely is applicable to vital phenomena only, aggregation to non-living matter only—evolution *from* already existing centres, movement *from* a spot, movement *towards* a spot—centrifugal, centripetal—towards, away from—to, from. If this be so, aggregation and evolution are *opposed* and cannot involve the same particles of matter; and the genesis of bodies "celestial" can hardly proceed like the "genesis" of living organisms terrestrial. Aggregation of lifeless particles seems therefore to belong to a category far away from that to which living growth belongs. *Aggregation* is absolutely different in essential nature from *growth*, and the two processes are absolutely opposed and cannot possibly affect the same particles at the same time. *Evolution must be restricted to the living world* or it can have no meaning.

So far, then, I feel compelled to maintain that between life and non-life the difference is *absolute*, whether we consider the life of the lowest fungi growing and multiplying in teeming millions at this moment upon every dead moist leaf, or the life of the so-called cells of the wonderful grey matter of our own cerebral convolutions.

I am, Sirs, yours faithfully,

Nov. 7th, 1898. LIONEL S. BEALE.

"A CASE OF DEATH UNDER CHLOROFORM, WITH REMARKS."

To the Editors of THE LANCET.

SIRS,—In sending some comments on the article under the above heading by Mr. Alexander Wilson, published in THE LANCET of July 30th, 1898, I must first apologise for the delay, which has been to a great extent unavoidable.

Firstly, I would say that the considerable fulness of detail given in the description of the case is a great improvement on the manner in which his former cases, published in THE LANCET of Sept. 11th, 1897, were described. This may or may not be due to my criticisms on them published in THE LANCET of Nov. 13th, 1897, but whether that is so or not the result is so far satisfactory. I say "so far," because in the case under criticism the description of the essential part of the case is second-hand. Mr. Alexander Wilson ought certainly to have asked the qualified medical man who was personally superintending the administration of the anæsthetic to give a first-hand account of the essential part of the case. It would have been easy to do so and it is absolutely necessary that the medical profession should have first-hand evidence of such essentials. With regard to the remarks on the case let me insist on one point. Surely any departure from normal anæsthesia is a sign of danger in chloroform administration and normal anæsthesia is characterised among other things by regular breathing with slight pallor.

It seems to me that the pith of Mr. Wilson's remarks lies in this sentence: "The practical point is that in these cases the first warning of danger is exhibited by a change in the circulation." Now, one has only to turn to the description of this case to see that, so far from this being so, the first departure from normal anæsthesia, and therefore the first sign of danger, was irregularity of respiration. It is so long since the case was published that I venture to quote the first items of clinical information given. They are as follows: "During the stage of excitement there was some struggling *with holding of the breath*, during which the lint was withdrawn from the face. Suddenly the patient began to breathe deeply and he became pale, the pupils were widely dilated, and no pulse could be felt." (The italics are mine.) Can anything be more evident than that the first departure from normal was a respiratory irregularity and that the syncopal symptoms

Digitized by Google

were subsequent to it? What, then, of these remarks by Mr. Alexander Wilson? "The symptoms in these cases indicate that the primary lesion is a paralysis of the circulation." "The first warning of danger is a change in the circulation." "The practical point is that in these cases the first warning of danger is exhibited by a change in the circulation." "It cannot be too much insisted on that as the primary lesion is in the circulation to the circulation must we look for the first signs of danger and to the improvement of the circulation must treatment be directed." They are all entirely pointless. Since the first sign of danger was in this case abnormal respiration it is scarcely worth while to pay any more attention to the remarks based on the opposite supposition.

With regard to treatment, the indications are plain: maintain absolutely regular respiration from beginning to end of the anæsthesia; do not early in the anæsthesia give the vapour in such concentration that the patient holds his breath; remember that a strength of vapour which one man will breathe with ease will so irritate the laryngeal mucous membrane of another that there will follow spasmodic adduction of his vocal cords and holding of the breath; and remember, too, that during all this time the chloroform imprisoned in his lungs is being absorbed with perhaps fatal effect. Later, too, be equally careful to maintain regular breathing, remembering that irregular breathing may mean either too much or too little chloroform (a point to be determined by other signs), and that either condition is one of considerable danger. With regard to the giving of ammonia vapour bear in mind that it equally with chloroform vapour may produce laryngeal spasm in the first stage of chloroform anæsthesia and plunge a patient from a condition of comparative safety into one of imminent danger. Seeing that Mr. Alexander Wilson has published several chloroform fatalities in his own practice, and that he makes a special point of the danger from syncope due to chloroform poisoning, and therefore presumably takes special pains to note the state of the circulation during his chloroform administration, would it not be worth his while in the future to direct his attention to merely maintaining regular respiration? The result, should he do so, can scarcely fail to be satisfactory to all concerned.

I am, Sirs, yours faithfully,

CLAYTON A. LANE, M.D. Lond.,
Mussooree, Oct. 19th, 1898. Lieutenant, I.M.S.

"A DEFENCE OF THE MIDWIFE."

To the Editors of THE LANCET.

SIRS,—In your annotation under the above heading in THE LANCET of Nov. 12th, pp. 1283–84, you say: "No Midwives Bill which we have yet seen contains any provision for ensuring that in every serious case a lying-in woman, however poor, shall have the benefit of qualified medical attendance, and without such provision no Midwives Bill should pass." In my Sick and Obstetric Nurses Bill, already reviewed in your columns, special provision is made for this very thing and by Clause 3: "It shall be unlawful for any person (male or female) to assume the title of midwife, or to practise as such, or to act as a sick or obstetric nurse for gain or otherwise, without the supervision and control of a fully-qualified and registered medical practitioner. Any person infringing this provision and neglecting or refusing to send for medical or surgical aid at or immediately after a confinement shall be liable to a fine of £10 or imprisonment for a month in default." Surely this is strong enough and the *modus operandi* is worked out in the schedules to the Bill. The Bill is printed in full in the *Medical Magazine* for March, 1898.

I am, Sirs, yours faithfully,

East Sheen, Nov. 14th, 1898. ALEXANDER MCCOOK WEIR.

"THE ETHICS OF CLUB PRACTICE."

To the Editors of THE LANCET.

SIRS,—I have read with interest and fellow-sympathy the letter *re* the above in THE LANCET of Oct. 15th. Leaving the possible legal obligation to pay the bill out of the question, should "Beta" pay it he will find that the smoothness and friendly feeling which have characterised his relations with the club members for thirty years will speedily disappear and that it will only be the thin edge of the wedge and the signal for other malcontents to be on the war-path, and that he will very soon be pestered with similar bills from quite unexpected quarters on account of some fancied neglect, and if he makes the dangerous precedent he will find a large hole made in the receipts from his clubs. So long as clubs exist so long will like cases crop up. There are always so many malcontents who are never satisfied, and very often it is those who get the most attendance who are the first to turn round and accuse you of neglect and will frequently tell you quite straight that because your money is sure you just do as you like. Then the medical practitioner, on the other hand, is called out over and over again, often at night and at unreasonable hours, to cases that are quite trivial, and if he dares to demur he is told that "he will be reported" or "he *must* come," or "he will be made to come or someone else will be called, and he will be made to pay the bill."

One knows when a message comes to attend a private case that it is necessary, but to attend a club case out of hours is in a great many cases unnecessary. The members pay so much and they must have their pound of flesh. Who of club doctors has not experienced the big strong man come to the surgery and after untying several large handkerchiefs hold out a slightly abraded finger, or slight crush, or small cut from a pocket-knife, &c., &c.? Who has not seen his surgery filled on a fine summer evening chiefly by women, who have just been passing the surgery during a walk and just dropped in to see what the medical man says about some very trivial matter, not only trivial in the doctor's estimation, but one which would be trivial also in a private patient's eyes? The private patient would not waste a fee on such a small matter, but the club patient has nothing more to pay no matter how often he consults his surgeon, so he abuses his privileges. All this is very degrading, but will exist so long as clubs exist—and I suppose that will be until the end of time. If one could get club members to understand, as you point out in your leading article in THE LANCET of Oct. 22nd, that the medical man must himself, and he only, be the judge as to the urgency of the cases and the order in which they are to be seen things would go more smoothly. I think the great majority of club doctors will agree that I have in nowise overstated, in fact have understated, the annoyances attached to club practice. Clubs are pernicious for both sides—they take from the doctor his dearest possession, his independence, and very often put the club member in a false position.

I have never seen a club yet, and that may seem a sweeping statement, which did not possess its malcontents—some fewer, some more—and it is from them that bills for attendance emanate. "Beta" should strenuously resist paying. The matter will be brought before a meeting of the committee and he will probably find that it will decide in his favour, though most likely, so as to mollify the malcontent, with a rider or suggestion, if not actually a warning, to be more particular in future. "Beta" is singularly fortunate in having been thirty years without such an experience.

I do not wish to seem at all to class the whole of the members of clubs as so inconsiderate—quite the reverse. The great majority are grateful for your attention and will thank you for coming during the night or at inconvenient hours and will express regret at having to trouble you, and it is a pleasure to attend such people, for who does not appreciate gratitude? The mere monetary consideration is not everything. I hope I have not trespassed too much on your space.

I am, Sirs, yours faithfully,

Oct. 29th, 1898. CONSTANT READER.

THE FEE FOR THE REGISTRATION OF DIPLOMAS IN PUBLIC HEALTH.

To the Editors of THE LANCET.

SIRS,—In the "Abstract of the Principal Laws Affecting the Medical Profession" contained in a recent edition of the Medical Directory I read under "Registration" that "a registered practitioner who obtains a recognised diploma for proficiency in sanitary science, public health, or state-medicine after special examination in the United Kingdom is entitled to have such diploma entered in the Register," and further that "any registered person who obtains any ..... of the qualifications mentioned above other than the qualification in respect of which he was registered is entitled to have such ..... additional qualifications inserted in the Register ..... on payment of a fee of 5*s*." Recently

Digitized by Google

I wished to register a diploma in public health and went to the Registrar's office expecting to have to pay 5*s.* as usual, but to my dismay I was informed that the fee was £2.

Will you kindly enlighten me as to any reason there may be for thus taxing one particular branch of medical knowledge? On the face of it to me it certainly seems unfair.

I am, Sirs, yours faithfully,

Nov. 14th, 1898. D.P.H.

*** We sympathise with our correspondent in having to pay a fee of £2 for the registration of his diploma in public health instead of 5*s.* Five shillings used to be the fee in accordance with the rule that additional qualifications might be registered for that sum. But the fee was increased in 1893.[1] There is some reason, too, for the larger fee. The diploma is of a different kind from others and confers altogether a new qualification. Also in 1893 inspections of the examinations were instituted and these, of course, cost money, which it was thought, perhaps, should be provided for in this way.—ED. L.

A POINT UNDER THE PUBLIC HEALTH ACT.

To the Editors of THE LANCET.

SIRS,—Will you kindly help me as to the following? Section 124 of the Public Health Act, 1875, says "Any person who is suffering from a dangerous infectious disorder and is without proper lodging or *accommodation*, &c.," "may be removed, &c." Does the word "accommodation" in that section justify the removal of a child or person who cannot be sufficiently isolated (say for diphtheria) from the rest of the family (the patient being one of the same family)? Perhaps you will kindly refer me to some cases on the point. I am, Sirs, yours faithfully,

Nov. 15th, 1898. M.O.H.

*** This question has received various interpretations by different magistrates, but it has never been finally decided on appeal. Some have held that since the section is one of a group under the heading "Provisions against Infection" it has primarily to do with the protection of the healthy. But others have maintained that since one of the conditions named in the section under which compulsory removal of an infectious patient to a hospital is permitted relates to a sick person "lodged in a room occupied by more than one family" interference of the sort referred to was not intended where the patient was in a room occupied by members of his own family, provided that the sick person had "proper lodging and accommodation" for his own treatment and recovery. Owing to the differences of opinion which exist on this point it is generally deemed expedient in ordinary cases to rely rather on persuasion than on compulsion.—ED. L.

THE VACCINATION OF CLUB PATIENTS.

To the Editors of THE LANCET.

SIRS,—May I ask the courtesy of space in your columns to call the attention of my professional brethren holding posts as medical officers to friendly societies to the question of the admission of unvaccinated candidates to the medical benefits of these societies. When the older—the parent—societies were founded, from which juvenile branches have for the most part sprung, vaccination, more or less compulsory, was general throughout the country. Underneath the contract between medical officer and club lay, therefore, at this time the tacit assumption that the majority of the members entering the different lodges would be vaccinated. Circumstances are now altered. Not only has legal vaccination been for several years neglected but under the new Act it seems probable that primary vaccination among the uneducated classes will fall very largely into abeyance.

We must expect, therefore, from this time forward an increasing proportion of unvaccinated candidates, both juvenile and adult, for admission to the membership of these societies. Under these circumstances the conditions of contract between the societies and their medical officers are no longer what they were before the abandonment of vaccination, and it behoves each medical officer to endeavour to protect himself under the altered conditions. He has now laid upon his shoulders the increased responsibility, risk, and liability to expenditure arising from the presence among his club patients of a large body of members unvaccinated and therefore peculiarly susceptible to small-pox in its severest form. What that susceptibility is among unvaccinated children, both as to attack and as to a fatal issue when attacked, need not be argued here.

The report of the Royal Commission (Final Report, p. 58, par. 217) shows that among children between the ages of one year and ten, and counting as vaccinated all doubtful cases, the average fatality-rate in six carefully observed epidemics was fifteenfold higher among the unvaccinated attacked than among the vaccinated attacked. It is desirable, therefore, that those who hold positions as medical officers to these societies should decide, and if possible decide unanimously, as to the course which they will adopt in dealing with this matter. Several courses appear to be open: 1. Where medical officers are in a position to make their own terms they may refuse to accept unvaccinated candidates. 2. In less favourable circumstances they might accept them, but at an increased subscription adequate to the extra risk involved. 3. They might accept them, but with a saving clause, which should appear in writing, that the unvaccinated members when suffering from small-pox shall have no claim on the gratuitous services of the medical officer.

I shall be glad if this communication calls forth an expression of opinion from others who have considered this matter. I am, Sirs, yours faithfully,

Nov. 14th, 1898. A CLUB DOCTOR.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Progress of the Plague.—The Three Outbreaks in Bombay.—Concealment of Plague Cases.

A FEW odd cases of plague continue to occur in Karachi but Calcutta remains apparently free. The epidemic appears to be extending towards Madras, where some doubtful cases of fever have already been reported. In the Dharwar district and in Bangalore it is now raging with great virulence. When I reported that for some months past plague in Bombay city had been allowed practically to take its own course I referred to the comparatively mild steps which are now being taken, compared with the rigorous measures adopted by the late committee. There being now no compulsion patients are allowed to remain in their own homes and to have their friends around them. A certain number of dirty houses are cleaned or emptied and a certain amount of disinfection is employed, but as far as infection goes it may be said that plague has a clear field. Notwithstanding the confidence restored by these considerate measures the number of reported cases of plague falls very far short of the excess in the total mortality, which is probably the only true guide to any estimate of the prevalence of the disease. But the lesson I want to point out is that plague did not increase with the abandonment of the strict repressive measures but rapidly went down, and that now during the third outbreak, which has already lasted thirteen weeks, we are experiencing a mild attack compared with the two preceding developments. The following table shows the total mortality for each week since July 5th:—

			Deaths.				Deaths.
Week ending	July	5th	440	Week ending	Sept.	6th	869
,,	,,	12th	523	,,	,,	13th	823
,,	,,	19th	563	,,	,,	20th	748
,,	,,	26th	583	,,	,,	27th	864
,,	August	2nd	615	,,	Oct.	4th	1001
,,	,,	9th	655	,,	,,	11th	990
,,	,,	16th	743	,,	,,	18th	828
,,	,,	23rd	765	,,	,,	25th	711
,,	,,	30th	811				

The general mortality is about 500 a week, and it stood at about this figure during the early part of July. Any excess

Digitized by Google

over this is probably due to plague. It will be seen that the mortality rose almost continuously until it attained 1001 in the first week in October and that since then it has rapidly declined. All this time infection has had free play. The vast majority of cases have remained in their own homes, only a moderate proportion going to the hospitals. In the two previous epidemics the weekly mortality rose to over 1800 and over 2000 respectively. The justification of the present method of procedure lies chiefly in the fact that concealment of cases, either ignorantly or intentionally, is largely practised, and that compulsion, even in its old severe form, did not lead to the report of a larger proportion of cases than occurs at the present time. In short, the measures of severity were frustrated and consequently proved themselves to be practically useless. The milder measures have not been attended with that extension of the disease which the opponents of the "let alone" policy prognosticated. The late Plague Committee were erroneously given credit for the decline of the epidemic in the spring of 1897, but they only commenced their work during that decline and it can be pretty clearly shown that the outbreak had spent itself. During the second development, when their organisation was complete and when if they had power to control the course of the epidemic they certainly had the opportunity, plague pursued exactly the same course, if not a more virulent one. It may be said that for a city like Bombay sanitary organisations have proved themselves impotent to alter the natural course of a plague epidemic. Roughly, one in every forty persons was attacked in the first epidemic and about the same proportion in the second. Both epidemics lasted rather over six months. The disease exhibited similar stages in the epidemics at Poona and Karachi during the first and second developments in each city. When we look back on the history of these outbreaks it is evident that plague pursues epidemically a definite course. As there have already been more than thirteen weeks of the present third outbreak in Bombay it may be reasonably concluded that the decline since the beginning of October is a real one and not merely a lull before a more extensive advance.

Concealment of cases occurs everywhere, in the country as well as in the towns. The recorded mortality from plague must fall very considerably short of the actual figures. The Government of India in a recent letter state that "the information that has been gained regarding inoculation against plague by M. Haffkine's method is all in favour of the efficacy of the system. It has now become possible to agree generally that inoculated persons should be exempted from segregation unless they are actually attacked with plague." They go on to say that inoculated persons will still remain liable to evacuate infected houses, and when travelling will be kept under observation and subject to the disinfection of their clothes. It is now two years since plague first appeared. The efficacy of inoculation was proved twelve months ago. The Bombay Plague Committee and the Government were repeatedly asked to allow that inoculated persons should be exempted from segregation, but the plague authorities, and especially the Bombay Plague Committee, persistently refused to admit the benefit of inoculation. When the last outbreak of plague in Bombay was subsiding all measures were practically dropped, yet little or no harm seems to have resulted. If during the height of the epidemic there had been the option of inoculation for segregation thousands upon thousands would have accepted it in preference to detention in camps. Now that a third epidemic is commencing and the disease is spreading towards Madras the concession is granted. On and off quarantine has been more or less employed, but the system has practically broken down. It failed to prevent the spread of plague and it was extremely vexatious and unpopular. Very different to the measures attempted in Bombay and other parts of the Presidency were the precautions taken in Hyderabad. When plague appeared in certain villages orders were issued that no money was to be wasted on disinfectants. The means adopted were removal of the occupants of infected premises and burning the latter down. Probably these are the two most effective measures which can be taken. Compare with some of the above recent civilian orders the following. Ten days' segregation will be enforced for troops and followers moved during the ensuing relief season from any station which may have become plague-infected. Corps moving from an infected station or through an infected district will be conveyed by rail. Doubtless it is necessary to exercise extra precautions for the troops and they can be more readily carried out, but the military authorities do not yet seem to recognise that plague is only slightly contagious and that provided infected dwellings are avoided there is little or no danger in passing through a plague-stricken district.

Some returns have just been published in the *Government Gazette* concerning the outbreak of plague in various towns and districts of the Presidency which show amongst other things the decided value of evacuation of houses, especially when promptly carried out. During the wet season, when this measure was not possible, towns and villages suffered in consequence more severely. In Jalgaon (population 14,672) plague appeared on Dec. 6th, 1897. The town was quickly evacuated and the disease disappeared in March. Only 108 deaths occurred (0·7 per cent. of the population). In Nasik (population 24,429) plague appeared in October, 1897. Evacuation was carried out ward by ward and the town became free in March. Of the population 1·5 per cent. succumbed. In Malegaon (population 19,261) plague occurred in November, 1897. Here also evacuation was gradually carried out and the outbreak lasted until March. Of the population 1·6 per cent. died. In Ahmednugger (population 41,689) the outbreak commenced in September, 1897, and lasted until April. The town was completely evacuated by the end of December and the mortality was only 0·7 per cent. of the population. There being no regularity in the particulars furnished it is impossible to make a more complete comparison. In Belgaum (population 40,737) evacuation was carried out with apparent success, but re-occupation was permitted too soon. The disease quickly reappeared and the outbreak has continued to rise ever since. In other places where evacuation has not been practised, either on account of the rains or from imperfect administration, the proportion of the population attacked has been much higher. The incidence of the disease has, however, varied very considerably. Places which one would have imagined would early have been attacked have either escaped altogether or have experienced but a mild visitation. Again, other places without apparent cause have been almost decimated. As reported previously, Hubli and Dharwar are excellent examples of the immense benefits of prophylactic inoculation.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Salford Corporation Bill.

THE Salford corporation intend to introduce a Bill into Parliament during the next session which, if passed, will, amongst other things, greatly extend their means of controlling certain dangers to the public health. They will seek powers to compel the removal to and the retention in a reception-house for a period not exceeding fourteen days of persons living in any house in which a case of infectious disease has occurred if the medical officer of health considers this necessary for the protection of the public health; to prevent the holding of "wakes" on the bodies of those who have died from infectious disease; to prevent the removal of such bodies by rail without the certificate of the medical officer of health that satisfactory precautions have been taken; to impose penalties on parents or guardians for knowingly allowing children to attend school when infectious disease exists in the home and on teachers for knowingly admitting such children to school; to require milk-dealers to let the medical officer of health know the sources of their milk-supply and to furnish a list of their customers when required; to prohibit the sale of milk from farms where infectious disease exists; to obtain power to enter cowsheds, &c., and to examine the cows; to compel the owners of such cows to assist in making such examination under penalty; to ensure the notification to the Health Department of disease in cows and to make the selling of milk from diseased cows a punishable offence; to obtain powers to proceed against the original seller of diseased animals; and to regulate the manufacture and sale of ice-cream.

Victoria University.

A meeting of the Court of the Victoria University was held at Owens College on Nov. 10th under the presidency of Earl Spencer, Chancellor of the University. Dr. Bodington, Principal of Yorkshire College, was elected Vice-Chancellor for a term of two years and Professor Wilkins and Dr.

Digitized by Google

Leech were elected pro-Vice-Chancellors for the same period. The adoption of the report of the Council on the Preliminary and Entrance in Arts Examinations was moved by Professor Tout. The report ran:—

The Council, having at the request of the Court considered the resolution of Convocation that "it is desirable that there should be only one standard qualifying for entrance to the different faculties of the University," beg to report that it is in their opinion advisable to substitute for the present Entrance in Arts examination an examination the papers of which shall be the same as those of the Preliminary examination. In consequence of the requirements of the Medical Council it will not be possible to offer to students who enter the Faculty of Medicine the same number of options as is given to students entering other faculties, but provision is already made in the present regulations that any students who have satisfied the examiners in the Preliminary examination may at a subsequent stage pass in those subjects only which the Medical Council has made compulsory for the purpose of registration.

Consequent on this report, the Council recommended certain changes, which were set forth, in the statutes and regulations. Dr. Leech seconded the adoption of the report, and the motion was passed.

Death from Water-gas.

An inquest was held by the city coroner on Nov. 8th on the body of a man who had died at the Bradford-road Gas-works. In the course of his duty the deceased took off the covering of a water-gas cooling manhole in order to fix a blank flange or disc used for distributing water for cooling purposes. He had been shown how to do this by means of a hook without entering the manhole and had been cautioned against going into it under any consideration. However, he did go into the manhole, where he was overpowered by the water-gas. The yard foreman, John Mason—his name deserves mention—found him there and at great risk descended the hole himself to attempt his rescue. He was in turn almost overpowered and only just managed to scramble back. When he was got out the deceased was alive but unconscious. He was taken to the Ancoats Hospital, where he died the same day without having recovered consciousness. The coroner paid a well-deserved tribute to Mason's courage, and said that he did "a noble act in trying to rescue the deceased and the gas committee ought to be proud of him." We have heard much of late about the courage of our soldiers, and it is satisfactory to feel that the same trait runs through the whole population.

Bequests to Medical Charities.

The trustees of the late Mr. James Holden of Marland, near Rochdale, have promised a grant of £10,000 to endow a wing of the Children's Hospital at Pendlebury. They have also promised £10,000 to St. Mary's Hospital as an endowment of the new hospital which is being built in Oxford-road. By the will of the late Mr. Joseph Ellis, solicitor, besides legacies of £250 each to the Solicitors' Benevolent Institution and the Manchester Law Clerks' Friendly Society, the Manchester Hospital for Consumption, &c., the Manchester Royal Infirmary, the Southern Hospital and the Manchester Eye Hospital will each receive a legacy to the same amount.

Manchester Museum, Owens College.

Mr. C. B. Crampton, M.B. Edin., has been appointed assistant keeper in the Geological Department of the museum, in succession to Mr. Herbert Bolton.

Unusual Arrangements at the Edinburgh Royal Infirmary.

ON Monday, Nov. 14th, at the weekly meeting of the managers of the Edinburgh Royal Infirmary, Dr. John Wyllie, one of the consulting physicians to the institution, was appointed to the charge of Professor Fraser's wards during his absence in India. The proposal to make this arrangement emanated from Professor Fraser and the medical faculty in the university and it has now been accepted by the infirmary managers. The proposal has met with a keenness of disapproval on the part of the staff, always excepting the professors who support one another whatever their personal views may be, which has had few, if any, precedents within recent years. To understand the position aright excerpts from the minute sent from a meeting of the staff to the infirmary managers may be quoted; it says "they (the staff) are strongly of opinion that it would be unjust and inexpedient to replace a member of the acting staff by a member of the consulting staff, and have come to this conclusion for the following reasons: 1. There is in the whole history of the Royal Infirmary no precedent for the proposal now made. 2. On all previous occasions in the absence of a clinical professor or ordinary professor his place has been taken by another member of the acting staff, and since the appointment of assistant physicians the substitute has always been the assistant physician who was associated with the professor or physician then absent." It then proceeds to give examples of this having been the ordinary practice. To understand this aright it is necessary to state that each full physician, whether he be a university professor or not, has an assistant physician attached to his wards whose duty is to take charge of the wards and to conduct the clinical teaching in the absence of his senior from any cause. Most of the assistant physicians have sole charge for months every year; the four senior assistant physicians are men of long experience and have lectured and taught in the school of medicine for many years and are all men ready equipped to perform professorial duties at an hour's notice and frequently have to do so. In spite of that, this extraordinary proposal has met with the sanction of the managers. The minute sent by the staff was signed by 31 of the 41 members of the staff, and of the 10 who did not sign 7 are professors. It is much to be regretted that the University in its corporate capacity should so act as to arouse resentment and ill-feeling, the results of which are far reaching and can only be deplored by all right-thinking persons.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Outbreak of Fever in the Armagh Union.

AT the weekly meeting of the Armagh Board of Guardians, held on Nov. 8th, Mr. Patterson, dispensary medical officer (Caledon), reported that there was a serious outbreak of typhoid fever in a place known as Enagh and the outskirts of the town of Caledon. Five persons had been removed to the Armagh Union Fever Hospital. It would appear that bad drainage is the probable cause, as within a few yards of the doors of the houses where the outbreak occurred the main sewer of the lower end of the town passes and empties its contents into a covered tank on the opposite side of the road, and two of the gulley-traps are placed opposite the windows of these houses and are rendered both useless and dangerous by being used by the occupants of the houses as receptacles for refuse and filth. A similar outbreak occurred in this place some time ago. Mr. Patterson made a very complete report, recommending an analysis of the water-supply and a careful examination of all the suspicious premises in the town, &c., and it was finally decided to refer the whole matter to the Caledon Dispensary Committee.

The Typhoid Fever Outbreak in Belfast.

I am glad to report that the outbreak is gradually subsiding. The number of cases notified for the week ended Nov. 5th was 72, the numbers for the previous six weeks being 98, 125, 149, 151, 172, and 114 respectively. The death-rate for the same period from all causes was 26·2, while that from the principal zymotic diseases was 4·3.

The Drainage of Belfast.

A special meeting of the corporation was held on Nov. 9th to consider a proposed drainage scheme for the "Cregagh" district, which has recently come within the city boundaries. The matter was one of great importance, but in regard to it the most diverse views are held. Some think the scheme unnecessary at present, others that it is too expensive. Others question the apportionment of the cost, while the senior alderman, Mr. Lawther, advised that the time had come when the whole question of the sewerage of the city should be taken up. Belfast had, he said, now an area of 17,000 acres, 11,000 of which comprised the added area. Their system of sewers was inaugurated thirty years ago and he was of opinion that they should have a comprehensive scheme of drainage for the whole of the city and they should procure the best skill and advice it was possible to get and have a report on the whole subject. Apparently a large number of

Digitized by Google

the corporation have no feeling in the matter, as the meeting came to a collapse for lack of a bare quorum, although a number of professional gentlemen representing those interested in the matter were present with witnesses.

The Belfast Recorder and the Medical Superintendent of the Asylum.

Attention was called in THE LANCET of Nov. 12th, p. 1299, to the extraordinary action of the Belfast Recorder, who declined to allow Dr. Graham, medical superintendent of the asylum, any fee for making an affidavit in reference to the condition of a lunatic and for attending in court. The Recorder made this ruling on the ground that, being a public servant, Dr. Graham was paid for that duty by the Government, and, further, he stated that his (Dr. Graham's) predecessor did not make such charges. At the usual meeting of the asylum governors on Nov. 14th Dr. Graham referred to the lecture which he had received in court from his Honour the Recorder and which had been published in the Belfast papers of Nov. 8th. Dr. Graham said that he could prove that his predecessor (Dr. Merrick) did charge fees for making affidavits on the mental condition of patients under his care and he read letters to show that the custom he had followed of charging a fee was the usual one. In the first letter Mr. Colles, Registrar in Lunacy, Four Courts, Dublin, writes, under date of Nov. 9th, that in his opinion the medical officers of district asylums are, as regards the giving of evidence in civil proceedings, in the same position as any other medical man. "That," he says, "is the principle on which successive Lord Chancellors have, without any exception, acted during the twelve or thirteen years that I have been here." "Asylum officers," he adds, "are frequent witnesses in lunacy cases before the Lord Chancellor in cases where the patient is under their care and their fees are always paid as a matter of course." The other communication read by Dr. Graham was from Mr. Smith, Office of Lunatic Asylums, Dublin Castle, and is dated Nov. 12th. In this letter he writes to Dr. Graham: "With reference to your communication of the 7th inst. asking if you can be compelled to make an affidavit and attend in court to give evidence on the mental condition of a patient under the care of the county court without being paid a fee, I am directed by the inspectors to state that they have not yet been able to obtain legal opinion on the question, but so far as the custom in other parts of Ireland is concerned they can state that in all such cases within their knowledge the resident medical superintendents of district asylums have always received fees for making affidavits and giving evidence in court relating to such patients."

Report on the Health of the City of Belfast for the year 1897.

It is interesting to note that the total deaths from zymotic diseases during 1897 was 1111 as compared with 1005 in 1896. The deaths registered under most of the zymotic headings were fewer in 1897 than in 1896, but in the former of these two years there were 336 deaths from typhoid fever and 355 from diarrhœa, as compared with 136 from typhoid fever and 206 from diarrhœa during 1896. Dr. Henry Whitaker, medical superintendent officer of health and author of the report, states that whilst typhoid fever occurred in 2·7 per cent. of the houses having water-closets, the houses with privies had 5·5 per cent. The disease was not confined to any district of the city, but it is a curious fact that the two districts (Dock and Millfield) which in his opinion were the most insanitary were those in which typhoid fever was the least prevalent.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Aneurysm by Subcutaneous Injections of Gelatin.

AT the meeting of the Academy of Medicine held on Nov. 8th M. Lancereaux answered certain objections to this method of treatment which had been put forward by MM. Huchard and Laborde. M. Lancereaux referred to some experiments which he had made upon animals, which showed that in a very short space of time after the injection of gelatin blood drawn from the general circulation would coagulate in a few minutes. In man after an injection he had never seen coagulation occur anywhere else than in the aneurysmal sac. The operative technique of the injection is as follows. White gelatin in a quantity of from 4 to 5 grammes is dissolved in a 7 per cent. solution of sodium chloride in measure 1000 to 2000 c.c. The solution is placed in a flask which is sealed and then sterilised with its contents at a temperature of 120° C. For the injection a flask of the capacity of 500 c.c. is got ready, fitted with a cork and two tubes like a wash bottle. The long tube is connected with a sterilised needle and the short tube with an indiarubber air-ball. The gelatin is liquefied in a water bath at a temperature of 35° C. and poured into the flask which is also kept in a water-bath. The injection is made slowly into the subcutaneous tissues and should take fifteen minutes. Thus performed it is not painful and no reaction follows. It should be repeated every six or eight days until the sac is obliterated. M. Lancereaux concluded by saying that this method, if carried out with care, gave excellent results in the most desperate cases.

The Surgical Treatment of Ptosis.

At the same meeting of the Academy of Medicine M. Motais introduced details of a new method for the treatment of ptosis. M. Motais considers that the anatomical and physiological connexions of the muscles which elevate the eyeball and the upper eyelid afford good grounds for supposing that the action of the one can supplement that of the other. Acting on this theory he has invented an operation which he has already practised in five instances. This operation, which consists in grafting the superior rectus to the eyelid, is of course of no use in those cases of ptosis where this muscle is paralysed as well as the levator palpebræ. Grafting the eyelid will suffice in most cases of ptosis, but where the eyelids are much thickened a combination of grafting and resection must be employed. The results obtained are practically perfect, the normal physiological conditions and movements of the eyelid being restored.

The Painless Treatment of Cracks in the Nipples.

At the meeting of the Obstetrical Society held on Nov. 10th a paper was read by MM. Maygrier and R. Blondel upon the Treatment of Forty Cases of Cracked Nipples at the Charité Hospital. They had dressed the cracks with orthoform which brought about complete anæsthesia during suckling and kept the cracks aseptic. The application of the powder causes only slight smarting. The infant was put to the breast a quarter of an hour afterwards and sucked eagerly, as orthoform has neither taste nor smell. The anasthesia persists for some time. MM. Maygrier and Blondel made trial of orthoform powder alone, of orthoform followed by a moist dressing of boric acid, and finally with a strong alcoholic solution of orthoform dropped into the cracks. They considered this last method the best for it caused no more initial smarting, but it quite did away with infection of the breast, probably because the solution was able to penetrate into the recesses of the fissures.

The Toxicity of Appendicitis.

At the meeting of the Academy of Medicine on Nov. 8th M. Dieulafoy argued that appendicitis is not only infectious but actually toxic. This theory explains those grave and sometimes fatal effects which supervene in cases of patients attacked with appendicitis. M. Dieulafoy related the case of a young man, aged twenty years, who had walked into the hospital. He was slightly jaundiced and complained of abdominal pain which had lasted for four days. The seat of the greatest pain was at MacBurney's point. The urine contained urobilin and albumin and his temperature was 37·4° C. (99·3° F.). The pain gradually diminished, he had no signs of peritonitis, and there was no puffiness in the iliac fossa. Laparotomy was performed and the parts were apparently healthy, but on passing the finger into the true pelvis a collection of foul-smelling pus was opened up and the appendix was bathed in this. It was exceedingly swollen and gangrenous in places, so it was removed and the patient recovered. The gravity of these lesions in no way corresponds with the gravity of the symptoms. The appendicular toxins may impair the action of the liver and the kidney, the result being urobilinuria, symptoms of which are frequently observed in the course of an attack of appendicitis. The toxæmia may be only very slight or it may be intense and even fatal. It is therefore necessary to make up one's mind so as to act at once. There is a toxic centre which it is necessary to do away with as soon as its presence is obvious. Jaundice, a sign of the invasion of the liver, is often a warning signal

Digitized by Google

of very grave toxæmia which acts upon the nervous system. The only means of coping with this disease is to do away with the toxic centre. With a correct diagnosis and an operation performed in good time all these disasters may be avoided, for no one, M. Dieulafoy urges, ever ought to die from appendicitis.

Matriculation Fees in the Universities.

The readers of THE LANCET are already conversant with the agitation set up among the students of medicine at the University of Paris against the new regulation by which admission to the library to the Faculty of Medicine is only to be procured by payment of a fee. Dr. de Lavarenne has set out the causes which made the University take this step in a long and very detailed statement. According to the new law the State revenue and the University revenue are very definitely allotted. The State pays the expenses of all the professors and administrative staff, but all questions of upkeep and various other expenses are laid to the charge of the University. The State only takes over the graduation fees and the University takes all the others, but this latter body has in addition the right of receiving legacies. As a matter of fact, although these laws were laid down with the view of favouring the University, a deficit for this year exists of 46,000 francs. In two or three years' time, it is hoped, legacies which will doubtless come in will have wiped off this deficit, but it was with the view of liquidating this year's debt that the University had imposed new fees, and among others the one dealing with the right of entry to the library. With the view of enabling his readers to compare the differences existing under the old regulations and the present ones M. de Lavarenne brings forward figures to prove his point. In 1896, when the State took all the fees and equally paid all the expenses the State received fees brought in by all departments of the University, amounting to a total of 820,150 francs. On the other hand, it paid personal expenses, laboratory expenses, building and furnishing charges, lighting, warming, printing, and office expenses, examination expenses, museum charges, laboratory and practical work expenses, prizes and medals—a total of 357,565 francs. In addition to this it paid the salaries of all the staff, both teaching and administrative, amounting to 1,080,975 francs, and gave a sum of 39,950 francs as well for library staff expenses. In 1899 the State will pay as formerly the expenses of the teaching and administrative staff, say 1,111,600 francs; it will also pay the library expenses, but, as has been said already, it will not incur any further charges. The fees arising from graduations will be the sole fees which the State will take in future; they amounted in 1896 to 509,027 francs. Consequently if it be considered that 820,000 francs is the total income (*le total des recettes*) of the University, and of this the State will take 509,000 francs, it necessarily follows that the University will only have 311,000 francs left to pay all the expenses of the Faculty of Medicine. In the days when the State paid everything the share of the Faculty was 357,565 francs, so that under the present regulations there is a deficit of 46,000 francs.

Nov. 15th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Medical Officers for Schools.

THE municipal authorities of Berlin have decided to appoint medical officers to the municipal schools. This step will certainly meet with the general approval of the medical profession which has for a long time past recommended medical supervision of schools. According to the instructions drawn up by the municipal school board the duties of these medical officers will be as follows: (1) They will examine children as to their state of health before they enter a school; (2) in cases of bodily or mental abnormalities they may recommend the adoption of special instruction; (3) they will have to look after children who are absent from school without sufficient reasons; (4) they will have to advise the headmaster in cases of infectious diseases; (5) they must give notice to the school board when they have found the health of the children unfavourably affected by the unhygienic conditions of a school; (6) they will have to be present at a certain hour at the school once a fortnight so that the masters may obtain their advice in individual cases; (7) they will have to control the class-rooms without reference to the hours of instruction; and (8) all the medical officers to schools will have to meet regularly under the presidency of a member of the school board to discuss matters relative to the hygienic conditions of schools, &c. The duties of these medical officers will be thus rather complex and a good deal of tact will be required on the part of these gentlemen to avoid friction with the teachers or with the family medical attendants of the children. A large proportion of school managers and teachers is opposed to the appointment of these medical officers because they are anxious that their own authority shall be supreme in everything that belongs to the schools and they are of opinion that the medical men may eventually undermine discipline. These apprehensions, however, seem to be unfounded, for a similar system has given satisfactory results in other towns, as, for instance, in Wiesbaden.

Hydropathy and Vegetarianism.

The late Professor Baron, a member of the faculty of law at the University of Greifswald, has bequeathed a sum of 500,000 marks (£25,000) to the city of Berlin for the purpose of erecting a home for orphans. The late professor was a strong adherent to the principles of vegetarianism and in his will he stipulated that none but vegetarian food should be used in the home. In addition to being a fervent vegetarian he also looked on the medical profession with disfavour and there was therefore another paragraph in his will to the effect that medical men were excluded from the board of managers and that in cases of illness the advice of a "hydrotherapeutist" was to be obtained. The municipal council is in great difficulties in connexion with this legacy, especially its last-mentioned proviso. Our "ædiles," of course, would like to accept the large sum left to them and would like to employ it for the philanthropic work devised by the testator. But they cannot do so without strictly executing the peculiar provisions contained in the will. A sub-committee elected to find a way out of this dilemma has not been able to come to a definite opinion and the matter continues to be discussed both in the vegetarian and medical associations, one party asking the municipal council to accept, the other to reject, the sum given under such conditions.

Female Medical Practitioners.

The medical supervision of prostitutes and of women arrested for immoral conduct on the streets is exercised by the police medical officers and an unfortunate event has lately drawn public attention to the subject. A girl waiting one night in the street for a man to whom she was engaged to be married, who happened to be detained rather late, was charged by a man with having made immoral proposals to him. She was accordingly arrested by a policeman, taken to a police-station, and kept there till the next morning; she also had to undergo examination by the medical officer. The charge proved to be an act of revenge, and both the man who made it and the policeman were severely punished. This case caused a considerable sensation in Berlin. The journals pointed out that similar events may occur not infrequently and that women's feelings must be greatly hurt by medical examinations of this kind. In the hope of conciliating objectors the chief of the police proposed that the examinations of prostitutes should henceforth be made by medical women, a suggestion which was at once severely criticised in the medical press, the chief of the police being asked whether he did not know that legally qualified medical women do not exist in Germany and that all the ladies engaged in practice here are unqualified in the eye of the law since they hold none but foreign diplomas, obtained chiefly in Switzerland. The chief of the police then explained that the lady to be appointed would be regarded as an unqualified assistant to the police surgeon to whom she would be responsible, and who would decide what part of his duties he would delegate to his assistant. In this way the requirements of public opinion as well as the laws relating to medical qualifications would be complied with. As these proposals were obviously an evasion of the law some of the practitioners' associations have petitioned the medical chamber that measures may be taken to prevent an unqualified person from holding a Government medical appointment. They point out that if the prostitutes were entitled to decline to be attended by male practitioners a general precedent applicable to all classes of

Digitized by Google

society would be established. In fact, the Association of Female School Teachers has already asked the Municipal School Board that the certificate of health required for appointments at public schools should henceforth be given by female medical officers. Not only is there a strong agitation among the women's associations relative to this matter, but the cause is furthermore supported by a number of the younger medical men.

Periostitis of the Orbit a Complication of Measles.

A rare complication of measles is described by Dr. Strubell in the *Münchener Medicinische Wochenschrift*. A boy of sixteen years of age had a pyrexial relapse in the period of desquamation after measles. He complained of severe headache especially near the left eye, abundant discharge of tears, photophobia, together with œdema of the eyelids, chemosis, exophthalmos, and injection of the ciliary vessels. The cornea and the pupil were normal but there was severe pain at the edge of the orbit. The fever in course of time disappeared and when the inflammatory symptoms had decreased Dr. Strubell found a swelling of the inferior wall of the orbit. The swelling got better within a short time and it was therefore evident that it was due not to cellulitis behind the eyeball but to simple periostitis. A similar complication after scarlet fever in a child of eight years has been observed by Dr. Wagenmann and Dr. Krehl; all the symptoms disappeared within a fortnight.

(FROM OUR OWN CORRESPONDENT.)

The Connexion of Mosquitoes with Malaria: Who first Discovered it?

QUESTIONS of "priority" in scientific discovery are dear to the Italian mind to judge from the space their discussion occupies in journals professional and lay. I recently communicated the claims of the Roman school to having determined the fact that it is "zanzare" (mosquitoes) which convey the poison of malaria and I pointed out what Dr. Bignami had contributed in concert with Dr. Dionisi towards that demonstration. His "mosquito-hypothesis," according to one of his most strenuous vindicators (Dr. N. Arcangeli of the San Giovanni Hospital), dates as far back as 1894, but his means of putting it to the experimental test were so imperfect that he could get nothing but negative results. "Meanwhile," says Dr. Arcangeli, "the hypothesis sustained by him more than held the field and was accepted by Laveran, who had till then supported the 'water-hypothesis.' Professor Koch, on his visit to Africa, had also adopted it, but what he has done to reinforce it will not be known till his promised report sees the light. The next step in Dr. Bignami's researches was his working on the lines of Dr. Grassi (Professor of Comparative Anatomy in the University of Rome), who had come to the important conclusion that in malarious localities there are found some kinds of 'zanzare' which are not found in healthy ones, and that these could inoculate the special poison. Repeating his experiments," continues Dr. Arcangeli, "Bignami employed the mosquitoes indicated by Grassi" and proved his hypothesis that it is by such means that malaria is inoculated in the human subject. But now comes Professor Grassi himself in correction, if not in abatement, of Dr. Bignami's claims, and his letter (which appears in to-night's *Corriere della Sera* of Milan) is so important that I shall quote its leading matter, translating Professor Grassi's own words: "I do not ignore Bignami's merit in having rendered probable the hypothesis that malarious fevers come by inoculation from mosquitoes, and in having first tried experimental proof in that sense, together with Dionisi, who thereafter extended his friend's hypothesis and experiments to birds. The fact, however, stands that both of them supposed that the 'zanzare' and cognate insects inoculated malarial germs taken from the soil, *while their experiments* [the italics are Professor Grassi's] *were always negative*. I cannot keep silence on the fact that it was I who first thought and proved that in places where malaria can be developed in man there exist peculiar mosquitoes which are absent where malaria is not so developed. Let it be added that from this proof and from a series of demonstrations and experiments made by me coincidently with the said proof I was led to maintain that *special mosquitoes* play the part in malaria which the 'zecche' (the *schaflaus* of the Germans) perform in Texas cattle-fever, and to exclude the necessity of recurring to the hypothesis of malarious germs in the soil. Nay, I proposed to Bignami (who had this year experimented largely and always in vain with mosquitoes held by me to be innocuous) to renew the attempt with those special mosquitoes I had procured for him. He accepted the proposal and so made the experiment which I had not at the time the opportunity of carrying out—the experiment which consisted in getting the mosquitoes, by me determined, to puncture an individual who had long been punctured in vain by the mosquitoes held by me innocuous. The experiment which was therefore reduced to this—namely, to liberate my mosquitoes in a room, with healthy atmosphere, inhabited expressly by the individual referred to—succeeded perfectly. The reader can now see for himself what part of the merit belongs to Bignami and what to me." So far Professor Grassi. It will be of interest to know the distinguishing marks of his "special mosquitoes," so as, *inter alia*, to understand how it is that in Rome, where there are no mosquitoes properly so-called, malaria is prevalent, while in Florence, where mosquitoes (properly so-called) abound, there is no malaria at all.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

The Health of the British Troops in Cairo.

A STATEMENT recently published in the London papers that "there are about four deaths every day from enteric fever in the Cairo hospital," and that there are numbers of cases of "both officers and men," requires a little modification. For some days, it is true, there were as many as four deaths in a day and even more, but this was for very few days. Now the number of enteric cases is lessening and the severity of the disease is less, so that the death-rate as well as the sick-rate is lower. By the last weekly returns the Cairo strength is returned at 3623; the sick-rate is 365, and the number of enteric fever patients among the sick is 96. The remainder of the sick were chiefly affected as follows:—simple, continued, and other slight fevers, 28; dysentery and diarrhœa, 40; ague and remittent fever, 17; venereal diseases, 48 (which is relatively small); debility, 12; and gunshot wounds, 13. The cases of dysentery, which were never very severe, are no longer coming in, for the incubative period of dysentery is considerably shorter than enteric fever. The Citadel Hospital is not now inconveniently overcrowded and there are no longer patients in tents. There are now 6 officers ill in the hospital, 4 from the British troops and 2 from the Egyptian Army. The whole number of officers who have contracted enteric fever is 6, 2 belonging to the Cairo command and 4 to the Alexandria garrison. Unfortunately, 3 of the latter have died. The officers have suffered from enteric fever and from all other diseases much less in proportion than the men. The Camerons head the sick-list with 90 of their men, and it is worth noting that the company which visited Fashoda has suffered from enteric fever and from dysentery considerably more than any other company in the same regiment. The Seaforths have 80 sick and the 21st Lancers have 40 in hospital, but one-third of these supply the few wounded who still remain.

The British Troops in Alexandria.

Out of a garrison of 1550 there are 198 sick, 61 of them being returned as "enteric." The other important figures in the weekly return are: venereal, 38; remittent fever, 17; dysentery and diarrhœa, 14; Mediterranean fever, 12; debility, 9; tubercle, 4; and gunshot wounds, 4. It is noteworthy that eye diseases are represented by 6 cases in Cairo and 2 in Alexandria, and that at no time has there been any serious ophthalmia. This is considerably different from the French expedition in Egypt a hundred years ago when the troops suffered terribly and two of Napoleon's generals each lost an eye from ophthalmia. The Fusiliers at Alexandria contribute now 57 to the sick-list, while there are 33 from the Gordons who are fresh from India, besides a large number of sick soldiers left behind by regiments which have now gone away.

A Comparison of Enteric Fever Occurrences with Former Years.

None of the enteric fever above mentioned has been caught in Cairo; already there have been 350 cases traced to the expedition this autumn. The soldiers who did not go to the front have not suffered from enteric fever, and the same applies to the barracks full of women and children. In 1897 there were only 30 cases of enteric fever in the army in all Egypt out of an average strength of 4450. This is not a large number when it is remembered that the young soldiers are at the most susceptible age and that in the bazaars they drink all sorts of foul liquids. In 1896 there were 97 cases of enteric fever in Egypt, but 47 of these were traced to the Dongola expedition, so that the number of Egyptian cases was 50. This, again, was an improvement on 1895, when there were 76 cases recorded. This gradual diminution from 76 to 50 and again to 30 is believed to be due to the extra precautions taken in barracks and hospitals to supply filtered and boiled water to the men.

The coming Cairo Season.

In spite of the absence of the German Emperor the season promises to be exceptionally good. The principal hotels have already double the number of visitors which they had last November and most of the dahabiyehs on the Nile have been engaged. Two new hotels will be opened next month and several existing ones have enlarged their premises during the summer.

Cairo, Nov. 8th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

A Medical Bill for New South Wales.

ONCE more a Bill has been introduced into the Legislative Council of New South Wales to regulate the practice of medicine. In addition to the usual clauses as to persons who not being legally qualified medical practitioners within the meaning of the Act take any name implying qualification the Bill contains clauses referring to persons advertising that they treat disease—to the effect that any person so doing must in such advertisement state Christian and surname in full and place them on any house referred to in the advertisement, and any person purporting to be but not being the person so stated in the advertisement is liable to a penalty of £20. In connexion with this subject a meeting of representatives of the various medical societies of New South Wales was held recently, at which it was resolved that the Council of the New South Wales Branch of the British Medical Association be requested to take action in urging on the Government the necessity for placing a Medical Act on the Statute Book and also an Indecent Advertisement Suppression Act. It was also suggested that a medico-Parliamentary committee should be appointed to watch all medico-Parliamentary matters.

Registration of Midwives in New South Wales.

The Bill to register Midwives has passed the second reading in the Legislative Assembly of New South Wales with some slight amendments in Committee. Dr. Graham, in moving the Bill, said the measure sought to place midwives under supervision and control by causing them to have their names placed on a Government register. The Bill would not prevent any woman carrying on the business of nursing, but to be a licensed midwife a woman would have to possess reasonable qualifications. Any woman who prior to the passing of the Act had carried on the business of a midwife would be entitled to a licence on production of a certificate of good character signed by medical men.

The Public Health of Tasmania.

The Central Board of Health, Tasmania, has issued its report for the year 1898. It appears that, in spite of epidemic visitations of typhoid fever, diphtheria, and scarlet fever, the general health of the colony has been good. The death-rate from all causes was very slightly lowered, being 11·53 per 1000 living. The increase in the number of notifications of disease was over 100 per cent., but the increase in the mortality from the same was under 5 per cent. The low mortality is attributed to the facts that the diseases were of a mild type and that more cases were treated in hospitals. The decrease in the mortality from diphtheria having coincided with a great increase in the use of antitoxin the Board "cannot but regard it as the cause." The incidence of typhoid fever as regards locality is noteworthy. The two principal cities—Hobart and Launceston—contributed 35 per cent. of the total, while six townships—Beaconsfield, Lefroy, Queenstown, Teehan, Macquarie, and Hamilton—contributed 43 per cent., and the remainder of the country districts only 21 per cent. The report does not explain this incidence, except that in Hamilton it "is certainly in part due to the inferior quality and insufficient quantity of the water-supply." The Board has drafted a Bill for Amending the Vaccination Acts. Although it believes "that the only efficient preventive measure against small-pox is universal vaccination," it has modified the compulsory clauses in accordance with the suggestions of the report of the recent Royal Commission on Vaccination in England. It is also provided that all parents may demand the use of glycerinated calf-lymph. Since this report was issued the Bill, as drafted, has passed both Houses of Legislature, and it will come into force on Jan. 1st, 1899.

Cremation in Victoria.

A Bill to regulate cremation has been introduced into the Legislative Council of Victoria. It provides that trustees of cemeteries may undertake cremation instead of burial and expend moneys for that purpose and charge fees. No cremation is to take place without the production of two special medical certificates. It is understood that the Bill was drafted by the Council of the Cremation Society, and chiefly by its President, Mr. Justin A'Beckett. At the annual meeting of this society held recently a proposal was mooted for starting cremation by private enterprise, but it did not meet with approval.

The Poisons Act in Victoria.

A Bill to amend the Poisons Act has been circulated in the Legislative Assembly of Victoria by the Government. It provides that the Poisons Act shall not apply to the sale of any poison when made up as a medicine by a legally qualified practitioner or chemist; or in the form of homœopathic medicine, unless in the crude state or of a greater strength than the third decimal potency; or to patent medicines, veterinary medicines, photographic materials, vermin destroyers, fly papers; or to wholesale dealings. The burden of proof that an article does not contain poison is placed on the defendant. A record of the sale of any article containing poison is to be kept and the wrapper of the article is to have the word "Poison" printed conspicuously thereon.

A Druggist Sued for £3000 for Negligence.

Reference has been previously made to the case of Mr. S. P. Williams,[1] of Fitzroy, Melbourne, who died from the effects of a hypodermic injection which was self-administered and which was alleged to be atropine, given him by a druggist in mistake for morphine. His widow has now brought an action against the druggist, claiming £3000 damages. The jury returned a verdict for the defendant. The judge in summing up said that negligence was admitted by the defendant and the real issue the jury had to try was whether death resulted from the negligence. Not one of the medical witnesses was able to say positively that death was due to atropine poisoning. Some of the medical witnesses did not think the appearances were in keeping with those of atropine poisoning. The two medical men who first saw the deceased were told by his wife that he had injected cocaine. The analytical chemist had failed to find any trace of atropine in the body. The deceased was a confirmed morphiamaniac and was also in the habit of injecting cocaine, and the medical evidence showed that the post-mortem appearances were perfectly consistent with cocaine poisoning.

Medical Litigation.

At the Newcastle District Court (N.S.W.) Dr. Harold Knowles Bean of Wallsend sued Dr. John Brady Nash of the same place for £200 for alleged slander. The plaint set out that in May last the defendant falsely and maliciously spoke of the plaintiff and of his treatment of a patient then under his care in the Wallesend Hospital, saying, "I consider your treatment of this leg the most disgraceful piece of surgery I have ever seen. You are the most incompetent surgeon I ever met and a disgrace to the hospital. I have watched

[1] THE LANCET, May 14th, 1898.

Digitized by Google

you before and just laugh at you." The plaintiff said that ever since he had settled in Wallsend there had been friction between himself and the defendant, and the latter had threatened to get him out of the place. His treatment of the fractured leg was perfectly warranted by the circumstances and the patient was in attendance to give evidence. Four medical witnesses gave evidence that Dr. Bean's treatment was correct. Dr. Nash gave evidence that the bones of the leg were necrosed, that the dead bone should have been removed sooner, and that the man had a stiff joint which should have been prevented. He had offered to withdraw the strong language he had used about Dr. Bean, but Dr. Bean also wanted him to admit that his opinion about the treatment of the case was wrong. The judge here suggested that the case should be amicably settled out of court. The parties retired and when the judge returned he announced that Dr. Nash had unconditionally withdrawn the charges made against Dr. Bean, and that he had admitted that they were without foundation and had expressed regret for having made them. The complainant accepted the apology and withdrew the plaint.

A Health Officer Suspended.

Mr. Collier, health officer of the shire of St. Arnaud, Victoria, has been suspended by the local council for neglecting to report a case of diphtheria which had been treated for some days in a private house in the centre of the town.

A Medical Officership at the Melbourne Benevolent Asylum.

As the outcome of the complaints as to not holding inquests at the Melbourne Benevolent Asylum the committee have decided to appoint a paid resident medical officer and have advertised the position at a salary of £200 per annum.

St. Vincent's Hospital, Melbourne.

The sisters of charity have purchased a fine site in Melbourne known as Chalmers' Church, formerly the property of the Presbyterian Church, on which it is probable that they will erect a new St. Vincent's Hospital, though they have not finally decided whether they will do so or erect schools there and enlarge the existing hospital on its present site. The sum already subscribed for building purposes amounts to £3000. The sisters hope to raise sufficient funds by a bazaar and carnival next Easter.

Retirement of Dr. G. E. Rennie.

Dr. G. E. Rennie of Sydney has resigned his appointments as deputy coroner, honorary physician and pathologist to the Prince Alfred Hospital, examiner in pathology to the University of Sydney, and honorary secretary of the New South Wales Branch of the British Medical Association. Dr. Rennie is leaving Sydney, and has been presented with addresses by the Council of the New South Wales Branch of the British Medical Association and the Sydney and Suburban Provident Medical Association, placing on record their appreciation of his valuable services, their regret at his departure, and their good wishes for the future. Dr. Rennie has for a long time held one of the foremost positions in the profession in Sydney as a highly scientific and energetic pathologist and physician and his departure will be a great loss to Sydney.

Removal of both Internal Jugular Veins.

In the *Intercolonial Medical Journal* for September, 1898, Dr. R. A. Stirling records a case of recurrent epithelioma of the glands of the neck in which he had removed the whole of the right sterno-mastoid muscle and the internal jugular vein from 1½ in. above its union with the subclavian to just below its emission from the skull with a mass of glands firmly adherent to it. About twelve months later recurrence necessitated a similar operation on the left side, which was successful.

Sept. 30th.

UNIVERSITY OF CAMBRIDGE.—The University Lectureship in Chemical Physiology has been filled up by the appointment of Mr. F. G. Hopkins, M.B., B.Sc. Lond., formerly of Guy's Hospital. During the past year 39 candidates out of 75 examined have received the Diploma of Public Health. Mr. P. J. A. Seccombe, M.A., of St. John's College, has been admitted to the M.B. degree. The first and second examinations for M.B. and B.C. will begin this term on Dec. 12th and the third examination on Dec. 13th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF THE COUNCIL.

AN ordinary meeting of the Council was held on Nov. 10th, the President, Sir WILLIAM MACCORMAC, Bart., K.C.V.O., being in the chair.

A letter was read from the Committee of the Medical School of St. Bartholomew's Hospital, calling attention to the serious dislocation of the teaching arrangements for students of the first year resulting from the altered regulations of the Combined Examining Board issued in July last in regard to Dissections, and strongly recommending the removal from the Regulations of the following clause, viz.: "This period of Dissection must be subsequent to having received instruction in the subjects dealt with under subparagraphs 2 (*a*) (Chemistry and Physics and Practical Chemistry), and (*c*) (Elementary Biology)."

The matter was referred to the Committee of Management to consider and report.

The Council adopted the report from the Court of Examiners and in accordance therewith directed that Diplomas of Membership should be issued to 120 candidates.

The Secretary reported the notices of motion sent in for the meeting of Fellows and Members on Nov. 17th.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

The annual meeting of the Fellows and Members was held on Nov. 17th at 3 P.M. There were present 104 Fellows and Members (including 14 members of the Council).

The PRESIDENT (Sir William Mac Cormac, Bart., K.C.V.O.) who was in the chair, presented to the meeting the Report of the Council for the year ending July, 1898. He referred to the success which had attended the representations of the Council in inducing the Government to establish a Royal Army Medical Corps and also the action of the Council in regard to a proposed interference with the practice of British medical men in Italy.

In moving the first resolution—

That this meeting congratulates the Council on the successful results of its representations in the matter of the reform of the Army Medical Service and trusts that it will now turn its attention towards remedying the notorious abuses which exist in connexion with civil medical practice—

Mr. GEORGE BROWN said that there were many great abuses which needed the earnest attention of the Council. Medical practice could only be carried on if the fees were on a remunerative scale.

The resolution was seconded by Dr. DANFORD THOMAS, who urged on the Council the importance of obtaining a new Medical Act which of itself would remedy half the existing medical abuses. If the Council would grant their support the movement would surely be successful.

The resolution was carried *nem. con.*

Mr. JOSEPH SMITH moved the second resolution—

That in view of the expressed opinion of the Council that it "represents the whole and therefore all parts of the Corporation," and in view of the fact that, so far as it has hitherto been possible to ascertain their sentiments both individually and at general meetings, the opinion of a large number of the Members is and has been for many years past that they should have some share in the election of the governing body, this meeting requests the Council to again consider whether some means cannot be found of fulfilling this desire—

and remarked that this resolution had appeared every year since 1884. He thought the best arguments in favour of the resolution were contained in a letter of Mr. Hutchinson which appeared two years ago. He proceeded to read the greater part of this letter.

Dr. THOMAS MORTON seconded the resolution, and urged the Council to withdraw from the impossible position taken up by them at their meeting in May, 1897, when they claimed to represent the whole College.

The resolution was supported by Sir ROBERT CRAVEN, Mr. HOUGHTON, Mr. WATTS, Mr. RICHMOND, and Mr. BELL, and was carried *nem. con.*

Mr. W. G. DICKINSON then moved—

That this meeting notes with satisfaction that the Council has at last definitely expressed its disapproval of canvassing for patients and of the employment of professional advertisements addressed directly to the lay public, and this meeting further trusts that the Council will extend its disapproval to the acting by Fellows and Members of the College as paid officials of any association which adopts these unprofessional practices—

and said that the Council did not seem to understand what

Digitized by Google

was wanted by those who brought before the Council cases of Members of the College who acted for medical aid associations. The important point in the whole matter was that advertising should be put down and no Member of the College should be allowed to accept a post under any advertising association.

Dr. HERBERT SNOW seconded the resolution, which was carried.

The next resolution—

That this meeting approves of the proposal to institute a gown for the Members of the College and trusts that the Council will see its way to carry this suggestion into effect—

was introduced by Mr. BRINDLEY JAMES and seconded by Dr. F. H. ALDERSON.

The PRESIDENT informed the meeting that the Council had already apppointed a sub-committee to consider the subject.

The resolution was carried.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen have passed the First Examination of the Board under the "Five Years" Regulations in the subjects indicated, viz. :—

Part I., Chemistry and Physics :

Adam, George Henry.
Avery, John.
Barnes, Ernest Charles Edward.
Bourgault, Auguste René.
Clowes, George Martin.
Coltart, Charles Herbert Romer.
Copland, John Brightman.
Cunninghame, Harry Bell.
Goldstein, John Leopold.
Graves, Harman John Howland.
Griffin, Ernest Harrison.
Grote, Robert George Ernest.
Howard, James.
Hughes, William Shelbourne.
Im Thurn, Robert Mackenzie.
Jeffery, Thomas Walter.
Johnson, Henry.
Johnson, Marchant Richard.
Lloyd, John Daniel Stuart.
Lovell, William.
Marshall, Oliver.
Porter, James Houston.
Power, Tom Costello.
Reatchlous, Henry Arnold.
Ring, Charles Augustus Eamonson.
Roberts, Frederic Emilius.
Stansfield, Walter.
Stephenson, John Leeming.
Thomas, Daniel Jenkins.
Waldron, Charles Edward.
Williams, Augustus Scott.
Wood, René William Louis.

Part II. Practical Pharmacy :

Alderson, Percy Francis.
Bateman, Ambrose Harold.
Bennett, Francis Grey.
Bird, Albert Edward.
Birt, Amelius Cyril.
Bond, Henry.
Bridges, David.
Brookes, James William Auston.
Bulteel, Cecil Edward.
Butler, Harold Branson.
Child, Harry Norman Rix
Claye, Everard.
Conolly, Noel Alfred William.
Cooke, Reginald Torriano.
Cope, Gilbert Edgar.
Cotton, Frederick William.
Crozier, George Rowland Henderson.
Dall, Elliot Wilfred.
Dyer, Walter Percy.
Ellis, Ernest Fitzgerald.
Enderby, Thomas Sydney Dawber.
Farquharson, Charles Henry.
Fletcher, George William.
Foster, Arthur Herbert.
Gee, Claude Alfred Heath.
Graves, Robert Kennedy Grogan.
Hagger, Roger Lionel.
Hartslet, Lewis Eccles.
Hope, Percy Lake.
Iles, Alfred John Hopkinson.
Keir, John Duncan.
Latham, Thomas Jones.
Lightfoot, John Henry.
Lipscomb, Neil.
Lloyd, David George.
Lowe, George Carter.
McIlroy, James Archibald.
McQueen, John Falconer.
Matheson, Farquhar Mackenzie.
Mieville, George Christian Blake.
Millar, Ernest Richard.
Neil, William Herbert.
Nimmo, Wilfred Cowan.
Parker, Charles Seymour.
Petrie, Alexander Sturrock.
Reid, James Derham.
Richard, George Herbert.
Rose, Edmund Frederick.
Rose, Thomas.
Row, Edward Reginald.
Scoones, Harold Edward.
Sheehan, Michael.
Spencer, Sandy.
Swindale, Henry Vernon.
Turner, Harry Stanley.
Vaughan, John C. F. Dudley.
Walters, Henry Blanchard.
Watson, Cecil Francis.

Part III., Elementary Biology :

Bishop, Thomas Henry.
Le Bas, Dumaresq.
Stephenson, John Leeming.

The following gentlemen have passed the First Examination of the Board under the "Four Years" Regulations in the subjects indicated, viz. :

Part II., Materia Medica :

Cooke, Percy Seymour.
Garman, Joseph Marcus.
Higgs, Thomas Frederic Walker.
King, Thomas Arthur.
Shanks, Henry Priest.
Whalley, Edgar.

Part III., Elementary Physiology :

Cope, Ricardo.

FOREIGN UNIVERSITY INTELLIGENCE.—*Gratz :* Dr. A. von Rosthorn of the German University of Prague has been appointed to the chair of Midwifery and Gynæcology in succession to the late Dr. von Rokitansky. Dr. Oskar Zoth has been appointed Extraordinary Professor of Physiology.—*Munich :* Dr. Jakob Berten of Würzburg has been appointed Extraordinary Professor of Odontology.—*Utrecht :* Dr. B. J. Kouwer of Haarlem has been appointed to the Professorship of Midwifery and Gynæcology.—*Vienna :* Dr. Heinrich Obersteiner has been promoted to an Ordinary Professorship of Neurology.—*Zürich :* Dr. von Frey of Leipsic has been appointed to the chair of Physiology.

VACCINATION AT CARDIFF.—At a meeting of the Cardiff Union Vaccination Committee held on Nov. 7th it was stated that last year the births in Cardiff numbered 5784 and the vaccinations were 4794.

THE CANTOR LECTURES. — The next Cantor Lecture at the Society of Arts will be delivered on Monday, Nov. 21st, by Professor Vivian B. Lewes. The subject of the lecture will be Acetylene.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the President, Vice-president, and Council, held on Friday, Nov. 11th, Mr. Fred. W. Kidd, M.D., L.R.C.S.I., Master Coombe Hospital, was elected Professor of Midwifery and Gynæcology.

NEW WATERWORKS FOR SWANSEA.—The ceremony of cutting the first sod of the new Swansea Waterworks at Cray, Breconshire, was performed by the Mayoress on Nov. 10th. The plans are for a reservoir to contain not less than a thousand million gallons.

FORGING A DEATH CERTIFICATE.—On Nov. 7th a man was charged at St. Asaph with forging a death certificate. Defendant went to the St. Asaph registrar and produced a certificate of death of his mother-in-law, alleged to have been issued by Dr. Jones of Rhyl. He then asked for a copy for an insurance company. Defendant pleaded guilty and was fined the full penalty, £10 and costs.

THE LATE MR. LLEWELLYN COUCH.—A meeting was held at Swansea on Nov. 8th, presided over by the Mayor, at which it was decided to raise a fund for the widow and children of the late Mr. Llewellyn Couch and to perpetuate his heroic self-sacrifice by erecting a suitable memorial. The father and brother of the deceased are members of the medical profession practising in Swansea.

THE BRITISH MEDICAL TEMPERANCE ASSOCIATION. — On Nov. 9th a breakfast meeting was held at the Cannon-street Hotel, London, convened by the British Medical Temperance Association, to which students from the various London hospitals were invited. Seventy guests sat down. After the breakfast the President of the association (Dr. Sims Woodhead) spoke of the important influence they would be able to exert in their future practice if they were total abstainers. Many years ago it was the fashion to bleed and salivate, and when this was found to be injurious some of the older men said it was due to a change in the type of disease. He had no doubt that hereafter the same excuse would be made to account for the disuse of alcohol. Dr. Louise Appel also addressed the audience and strongly urged them to join the association, no pledge being required or subscription from students but simply the practice of total abstinence. Eighteen students joined the association.

A SANATORIUM FOR PHTHISICAL PATIENTS.—A meeting to consider a proposal for providing a sanatorium for phthisical patients in Yorkshire was held at the Mansion House, York, on Oct. 27th. The Lord Mayor presided and there was a numerous attendance, including the Marchioness of Zetland, the Countess of Harewood, Mrs. W. H. A. Wharton, Sir William Broadbent, Bart. (chairman of the Executive Committee of the National Association for the Prevention of Consumption), Mr. Malcolm Morris (treasurer of the association), and Sir J. Crichton Browne. Sir William Broadbent in the course of an address which he delivered gave a very encouraging account of the results obtained by the open-air treatment of tuberculosis. Mr. Malcolm Morris referred in terms of warm commendation to the efforts made by Mrs. W. H. A. Wharton and the Marchioness of Zetland on behalf of a sanatorium in Yorkshire. On the motion of the Marchioness of Zetland, seconded by Dr. Eddison, it was resolved: "That it is desirable to found a sanatorium for the cure of consumption in Yorkshire," and it was decided to form in York a local branch of the National Association for the Prevention of Consumption.

THE STUDY OF LEPROSY IN BRESLAU.—Arrangements are being made for the careful study and treatment of leprosy in the Breslau University Clinic for Skin Diseases, the patients being brought from Eastern Prussia with great precautions as to isolation and disinfection of the railway carriages.

THE PLAGUE.—The newly appointed scientific Commission for the investigation of plague in India will unfortunately find a great deal to engage their attention on arrival in that country, for the latest telegraphic intelligence from India does not show that there are any signs of abatement of the disease.

PRESENTATIONS TO MEDICAL MEN.—On Nov. 5th, at Sherburn, on the presentation of certificates and medallions to the members of the South Milford (North-Eastern Railway) Ambulance Class, Mr. E. P. Pickersgill, L.R.C.P. Edin., M.R.C.S. Eng., was the recipient of a carriage clock in token of appreciation of his services to the class.—Mr. J. Todd, M.R.C.S. Eng., of Gateshead-on-Tyne, who is one of the town's oldest medical practitioners, and who has been for twenty years the medical officer of the Gateshead Branch of the Boiler-makers' Iron and Steel Ship Builders' Society, has been entertained to supper at the Royal Hotel, Gateshead, by the present and past officials of the branch, and presented on the occasion with a gold-mounted umbrella as a mark of the high esteem in which he is held by them.

MUNICIPAL HONOURS TO MEDICAL MEN.—In the Borough of Tunbridge Wells at the recent municipal elections the following members of the medical profession were duly elected: Mr. George Abbott, L.R.C.P. Lond., M.R.C.S. Eng.; Mr. Lawson Dodd, L.R.C.P. Lond., M.R.C.S. Eng; and Mr. Norman Hay Forbes, F.R.C.S. Edin., L.R.C.P. Lond., M.R.C.S. Eng.—Dr. F. J. A. Waring was elected an alderman at the first council meeting at Hove under the new charter of incorporation of that town.—Mr. Joseph Harper, M.R.C.S. Eng., L.R.C.P. Lond., J.P., has been elected an alderman for Barnstaple; Mr. George Swithin Adee Waylen, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., an alderman for Devizes; Mr. William Banks, M.B. Lond., M.R.C.S. Eng., an alderman for Falmouth; and Mr. James Bunting, M.R.C.S. Eng., L.S.A., has been appointed deputy mayor of Torquay.

ROYAL METEOROLOGICAL SOCIETY.—The opening meeting of the session was held on Wednesday evening, Nov. 16th, at the Institution of Civil Engineers, Great George-street, Westminster, when a report on experiments upon the exposure of anemometers at different elevations was presented by the Wind Force Committee. The experiments have been carried out by Mr. W. H. Dines and Captain Wilson-Barker on board H.M.S. *Worcester* off Greenhithe, and among the conclusions arrived at was one that no other form of anemometer offers such advantages as the pressure-tube from the fact that it can be run up and secured easily at the necessary height above a building and that the pipes and stays can be slight so as to offer no resistance to the wind or cause any deflecting current.—Mr. W. Marriott exhibited some lantern slides showing the damage caused by the tornado which burst over Camberwell about 9.30 P.M. on Oct. 29th. The damage was confined to an area of about half a mile in extent and within that space chimney-stacks were blown down, houses unroofed, trees uprooted, and windows broken.

MEDICAL REFORM.—On Nov. 5th the Gateshead Medical Association formally entered into affiliation with the Corporate and Medical Reform Association, Limited, as the result of two meetings held on Oct. 15th and Nov. 1st. The former was a meeting of the medical profession of Gateshead and neighbourhood convened by the local association, the President, Mr. J. H. W. Ridley, in the chair, to hear an address by Mr. R. B. Anderson, F.R.C.S. Eng., submitting as its representative the policy and proposals of the Corporate and Medical Reform Association. A resolution was passed in favour of the policy of the association, and a vote of thanks to Mr. Anderson for his address was carried by acclamation. Dr. Cox, who moved the resolution, said that he had always supported, and would continue to support, any association which offered a reasonable expectation of benefit to the body of the profession. He warned Mr. Anderson that the support of Gateshead would only be continued if useful work were seen to be in progress. Dr. Mearns seconded the resolution, which was supported by several others. At an ordinary meeting on Nov. 1st it was moved by Dr. Cox, seconded by Mr. Ridley (President), and carried unanimously: "That this association endorses the policy of the Corporate Medical Association, Limited, and will take steps to affiliate with it."—On Oct. 28th the New Cross Medical Society formally entered into affiliation with the Corporate and Medical Reform Association, Limited, pursuant to resolutions unanimously adopted at general meetings on Oct. 5th (Dr. C. P. Handson, President, in the chair), to support the association and coöperate in its policy and measures, and on Oct. 12th to affiliate with the association. The affiliation is to take effect from the date of the second resolution.

FRIDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

SATURDAY (26th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.), London Throat Hospital (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (21st).—SOCIETY OF ARTS.—4.30 P.M. Prof. V. B. Lewes: Acetylene. (Cantor Lecture.)

TUESDAY (22nd).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.15 P.M. Demonstration:—Mr. J. L. Thomas: (1) Penile Stricture from a Case of Urethrectomy; (2) Vermiform Appendix containing a large Concretion. 8.30 P.M. Papers:—Mr. E. Owen: A Distinct Variety of Hip-joint Disease in Children and Young Persons.—Mr. J. Hutchinson, jun., and Mr. H. L. Barnard: On an Improved Method of Treatment of Separation of the Lower Epiphysis of the Femur.

WEDNESDAY (23rd).—DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—4.30 P.M. Informal Exhibition of Cases. 5 P.M. Paper:—Mr. C. Williams: Congenital Syphilis: a New Theory. Dr. A. Hall (Sheffield): (1) Note on Eczema produced by Phenyl Hydrazin Hydrochlorate; (2) Photograph of a Case of Primary Syphilis with Two Hard Sores on the Hand.

HUNTERIAN SOCIETY (London Institution, Finsbury-circus).—8.30 P.M. Dr. T. G. Lyon: An Enquiry into the Production of Blood Plasma, its Vital Properties and mode of Nourishing the Tissues.—Mr. T. H. Targett; Two Cases of Cancer of the Uterus with Pregnancy.

FRIDAY (25th).—CHARITY ORGANISATION SOCIETY (Portman Rooms, Baker-street, W.).—4.30 P.M. Miss A. Hughes: District Nursing. (Course of Lectures on Medical Relief.)

CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Mr. W. G. Spencer: Gumma of the Liver—Cases in which Surgical Measures were followed by Relief.—Dr. M. Fletcher: Green Urine.—Mr. F. C. Wallis: Two Cases of the Effects of Gastric Ulcer treated by Operation.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

SUNDAY (20th).—SUNDAY AFTERNOON FREE LECTURES (South-place Institute, South-place, E.C.).—Dr. E. B. Forman: Medical London, with lantern illustrations. (Course of Lectures on Our Cities and Municipalities.)

MONDAY (21st).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Mr. G. C. Wilkin: Nasal Polypi.

TUESDAY (22nd).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-sq., W.C.).—3.30 P.M. Dr. Taylor: Cerebral and Spinal Paralysis in Children.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street, W.).—4 P.M. Dr. T. D. Savill: Cases of Hemiplegia and the Treatment of the Affection.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. P. Abraham: Syphilides.—Bethlem Hospital, 2 P.M., Dr. Craig: Puerperal, Lactational, and Climacteric Insanities.

WEDNESDAY (23rd).—HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. S. Martin: Asthma and its Treatment.

LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-st., W., 4.30 P.M., Prof. A. Wynter Blyth: Infectious Diseases.

Digitized by Google

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Dunn: Examination of the Eye.

THURSDAY (24th).—LONDON POST-GRADUATE COURSE.—Central London Sick Asylum Cleveland-st., W., 5.30 P.M., Mr. J. Croft: Clinical Lecture.
LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration to Senior Students.
CHARING-CROSS HOSPITAL.—4 P.M. Dr. Willcocks: Demonstration of Medical Cases. (Post-Graduate Class.)
THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Barlow.

FRIDAY (25th).—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Erysipelas and Suppuration.
WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Dunn: Examination of the Eye.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

"DOUBLE PERSONALITY."

UNDER the above heading Dr. William Lee Howard of Baltimore describes in the *Maryland Medical Journal* of Nov. 5th "a psychical condition which dissociates the elements of the mind and then combines them into a distinct separate and strange personality. During this state the individual has no recognition of his normal state. He bears a different name, has another occupation, perhaps resides in a different town from his own, acts rationally, and is fairly successful in his new vocation. He suddenly returns to his primary self, and goes back to home and business." The case was that of Mr. B., a respected business man, married, and the father of three children. His position caused him to travel extensively in America: from the Pacific to the Atlantic oceans, from the Gulf of Mexico to Hudson Bay. About ten years' ago he commenced to go away from home without giving any definite statement of where he was going or when he would return. Upon his return he would not, or could not, give any direct answer as to where he had been. On these occasions he appeared slightly dazed in memory and intellect and his appearance was that of a man who had aged greatly from want of sleep. Two years ago, in the month of October, he disappeared and no trace of him could be found until he returned home on Jan. 14th. A man who knew him in his own city found him a month prior to this date conducting a country cross-roads store on the upper Potomac. He carried on business under the name of Simpson and had been known under this name since he had been in the village. He did not know his former acquaintance, and the repeated mentioning of his true name "Mr. B.," he at first took as a joke, then became indignant and was so positive in stating that he was Simpson, giving his past history, stating that he was from Oregon, and going into full and complete details of his life and business in that State, that the former friend went away fully convinced of his mistaken identity. On Jan. 14th he appeared at his own house to the surprise and joy of his family. He was Mr. B. again, but no question as to his past whereabouts could he answer. Dr. Howard continues: "Appreciating his lapse of memory his wife persuaded him to consult me. In his normal condition I could elicit no information, yet he did his best to aid me. His memory of the last three months was a blank and he was pitiably nervous and worried. Without much difficulty he was hypnotised and through tentative suggestions he gradually veered around to his other personality. He said, when I suggested his name was unknown to me and he must tell me, 'D——n it, you know my name is Simpson; what do you want to bother me about it for?' ..... By this manner of questioning Mr. Simpson I found where the body of Mr. B. had been. The next day I hunted up Mr. Simpson's store, and found, indeed, that such an individual existed in the life of the village. Subsequent investigations cleared the whole matter satisfactorily as far as Mr. Simpson was concerned. ..... This man had passed through all the privations and excitement of the civil war. He received his discharge along with an unstable neurotic temperament, which demonstrated itself in a demand for alcoholic stimulants, which demand merged into the disease dipsomania. ..... His continued and reiterated statement that he came from Oregon can be traced to the fact that shortly after the war he had had some exciting and memory-marking episodes in that then wild and unsettled country."

DISEASED MEAT COOKED PREVIOUSLY TO SALE.

THE *Gazzetta degli Ospedali* of Nov. 3rd states that the municipality of Milan intends to provide an apparatus in which the flesh of diseased animals may be subjected to a steam heat of 115° C. (239° F.) previously to sale. It is considered that in this way wholesome food may be obtained from animals affected with tubercle, foot-and-mouth disease, and pleuro-pneumonia, as well as from those which have died from hæmorrhage or injury. The meat so prepared is as juicy as if cooked by the ordinary domestic methods and is in no way deteriorated as an article of food. Shops will be established for the sale of this meat; the price of which will be about 50 centesimi per kilo (2*d.* a pound); the juices which come from the meat in the process will be sold as soup *(brodo)* at 1½*d.* a pint.

THE CARRIAGE BY SEA OF INFECTIOUS CASES.

To the Editors of THE LANCET.

SIRS,—It has occurred to me that attention should be drawn to the risks incurred by healthy passengers making a long sea voyage. I have just reached South Africa from England. On the way out the next cabin to mine was occupied by a youth who had been suffering from pulmonary phthisis for a year. He depended for ventilation on the air from neighbouring portholes, which passed through a 6 in. opening running round the top of his cabin, which had no port. Unfortunately the sea was rough and my port was closed for 11 days (5 days consecutively once). The ventilation then became reversed, the air from the hatch and skylight passing over the phthisical youth and bringing germs, &c., into the *cul-de-sac* formed by my cabin. Apart from the unpleasantness of hearing him cough, &c., no disinfectants were used for his expectoration. He used the same knives and forks and china and glass as the other passengers, and these were naturally washed up with and dried on the same cloths as the rest. Now tuberculosis is regarded as infectious, is it not time that steamship companies should make some provisions to protect their healthy passengers, though the problem may not be an easy one?

I am, Sirs, yours faithfully,
M. W.

AN ACCOUCHEMENT ON THE TOP OF A TRAM CAR.

To the Editors of THE LANCET.

SIRS,—As an illustration of remarkable places to choose for accouchement you will perhaps be interested to know that in my capacity as police surgeon for Bow I was called by the police a short time ago at 9 P.M. to attend a woman who was about to be confined on the top of a tramcar in Bow-road. On getting there shortly after I found the tram run off the metals on to a siding and surrounded by a cordon of police to keep the crowd at a respectful distance. With the assistance of the police matron and a bull's eye lantern everything passed off very satisfactorily, the woman being safely delivered of an infant weighing not less than 8½ lb. They were removed home shortly afterwards on the ambulance and are both at the present moment perfectly well.

I am, Sirs, yours faithfully,
E. A. LIGHTBURNE,
Surgeon, K Division, Metropolitan Police.

Bow-road, E., Nov. 12th, 1898.

THE IMPORTATION OF MICROBES.

ACCORDING to the *Times* the Government of Victoria has taken a very decided line with regard to the importation of microbes. A medical man who recently returned to Melbourne from India, where he had been studying the plague, brought with him a stock of plague bacilli. The authorities of Melbourne strongly objected to the bacilli being imported and asked for their surrender. The medical man is said to have declined to give up the microbes unless compensated to the amount of £300, on which the authorities seized the culture tubes and destroyed them.

A QUESTION.

A, B, and C are practitioners in a country town. All are on the honorary staff of the local cottage hospital. There is a quarrel, a matter connected with the hospital, and B and C *resign*. Thus A is left as the sole honorary surgeon. D now comes on the scene and purchases A's practice and during the introduction by request of the committee assists A to do the work of the hospital. Finally A leaves the town and D is unanimously elected as honorary surgeon to the cottage hospital, which post he fills alone for a time. Then B and C are re-elected as honorary surgeons. D asserts that he is *senior* by priority of election. Is that so?

*** We consider that D is the senior, but under the curious circumstances related he would be well advised not to insist too much on his position.—ED. L.

"VEGETABLES GROWN ON SEWAGE SLUDGE."

"S. K. P." writes to us again upon this subject:—"I thank you for your reply to my question on the above subject in THE LANCET of Nov. 12th, but fear from its tenor that I did not make myself understood. You say, 'the depth at which the sewage sludge is placed (30 in. beneath the surface) is, we should imagine, too great to allow the cabbages to derive much manurial value therefrom, &c.' It appears from this that I conveyed to your mind the impression that there was 30 in. of earth, &c., above the sludge, whereas I intended to explain that the cabbages are planted in earth and dust-bin refuse of the depth of 6 in., beneath which is 30 in. of sludge thus. As this matter is causing a great sensation in the neighbourhood I should be glad to know if this further explanation will at all modify your reply."

*** Under the circumstances detailed it is not likely that the cabbages will be unwholesome. The cabbage is a short-rooted plant and will get most of its nourishment from the top 6 in. rather than from the bottom 30 in.—ED. L.

"SCARLATINIFORM ERUPTION IN INFLUENZA."

To the Editors of THE LANCET.

SIRS,—In reply to the query of "Eruption" in THE LANCET of Nov. 12th as to the appearance of a scarlatiniform rash in influenza let me state that I have noted such an eruption fairly frequently during epidemics of influenza. In my experience it differs from scarlet fever rash in appearing on all parts of the body (which show a rash) simultaneously and with equal distinctness, and in disappearing from all parts simultaneously. The temperature in such cases seldom exceeds 100° or 101° F. Sore-throat and albuminuria are rare in conjunction with the influenzal eruption. Desquamation may occur, but is usually more limited in extent than in scarlet fever and appears not so much in the form of flakes as in the form of fine powder or dust.

I am, Sirs, yours faithfully,
West Hartlepool, Nov. 14th, 1898. W. GRAY, M.D. Edin.

To the Editors of THE LANCET.

SIRS,—With reference to the letter of inquiry in THE LANCET of Nov. 12th from "Eruption" on the above subject, I beg to inform him that I have lately had a number of such cases as he describes. In some instances there is practically no difference between the character of the eruption and that of scarlet fever, but in the majority of cases it is somewhat of a mottled character. There is, however, never the strawberry tongue of scarlet fever, the throat is not so much affected, and the fever is of very short duration. Where the eruption is well marked desquamation often occurs. I have considered these cases to be a mixture of influenza and rubeola.

I am, Sirs, yours faithfully,
Brentwood, Nov. 14th, 1898. J. R. WHITE, M.B. T.C.D.

M.D.—Several high-class medical journals are published weekly in Germany and Austria. In Berlin are the *Deutsche Medicinische Wochenschrift* and the *Berliner Klinische Wochenschrift*, each of 12 leaves—i.e., 24 pages—and costing 6 marks per quarter; in Munich there is the *Münchener Medicinische Wochenschrift*; and in Vienna there is the *Wiener Medicinische Wochenschrift*, sent post free out of Austria for 24 marks per annum. All these are printed in Roman characters. The German dictionary published by Cassell and Co. will serve every ordinary purpose, but for reading medical works a dictionary of medical terms is almost essential. The "German-English Medical Thesaurus," published in 1895 by the author, the Rev. Henry Losch, M.D., of 4109, Pine-street, Philadelphia, U.S.A., is copious and good in the anatomical and pathological part. (Pp. 323. Price $2.50.) Sudthausen's "Sprachführer für die Aerztliche und Pharmaceutische Praxis" (two little volumes, price 4.80 marks; Leipzig: Eduard Besold, 1896) has fairly good lists of surgical requisites and pharmaceutical appliances. There are one or two more works of the same kind published in Germany. The German columns in the "Nomenclature of Diseases" may also be consulted with advantage.

E. H. S.—Medical Nursing: Notes of Lectures given to the Probationers at the London Hospital, by the late James Anderson, M.D., F.R.C.P. (London: H. K. Lewis. 1894.); Lectures on Medicine to Nurses, by Herbert Cuff, M.D. Lond., F.R.C.S. (London: J. & A. Churchill. 1896.)

Persevere.—To adopt the style of "Colonel" under the circumstances mentioned by our correspondent would not be in strict accord with any of the Royal Warrants. The titles applying to the active service have not, as yet, been conferred upon retired officers unless those officers are employed.

L.R.C.P., M.R.C.S.—Such a medical man has passed an examination in surgery and is admitted to the Medical Register as a fully qualified man on terms of equality with the rest of the profession. Under these circumstances we do not think the description need be cavilled at.

Senex.—The course in both cases is a matter of taste. There is no prescribed ritual. Different localities have different customs and it is well for the new-comer to consult an old inhabitant as to his procedure.

A Provincial Surgeon.—The letter is a little long for our columns and is, moreover, written on both sides of the paper, which gives great trouble to the printers. Also such a letter should be signed by its author.

F. C. J.—We do not give such advice. The questions can be answered by the medical adviser, to whom we shall be happy to give any assistance he may need.

Subscriber.—As our correspondent puts the case we do not see anything unprofessional or ungentlemanly in the conduct of the resident medical man.

Rural.—1. To make such calls is unusual and unnecessary. 2. It would be much preferable to give the address of an agent.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

IMPROVED OBSTETRIC REQUIREMENTS.

RISK OF PUERPERAL SEPTICÆMIA

IS REDUCED TO A MINIMUM BY USING

HARTMANN'S

COMPLETE

GUINEA OUTFIT FOR ACCOUCHEMENT.

It contains 3 different sizes of Hartmann's Absorbent Wood Wool Sheets, 4 dozen Hartmann's Hygienic Towelettes, Binder, Safety Pins, Antiseptic Ointment, Thread, Umbilical Pad, Fuller's Earth, Oiled Silk, Mackintosh Sheeting, &c.

It affords great cleanliness and comfort to the patient, and diminishes the risk of puerperal fever.

Too much attention cannot be given in selecting the best articles for use during confinement; and in the interest of their patients we ask physicians to recommend Hartmann's Complete Guinea Accouchement Outfit.

A Smaller Outfit is also put up, price 10/6.

REDUCED PRICES to DOCTORS & NURSES.

The above Boxes will be sent to any Medical Man or Nurse on receipt of 19/- or 9/6.

HARTMANN'S

Five Sizes—but one Quality.
From 6d. to 2s. per Doz.

HYGIENIC WOOD WOOL TOWELETTES.

Put up in the following sizes:—

In BROWN paper, -/6 per doz. size (our new halfpenny size).
In WHITE paper, 1/- per doz. size.
In BLUE paper, 1/4 per doz. size (new make).
In GOLD paper, 2/- per doz. size.
In YELLOW paper, 2/- per doz. size (special make for use after accouchement).

} Superior to any other make.

FOR HOME USE, DELICATE HEALTH, FOR LADIES TRAVELLING AND ACCOUCHEMENT THEY ARE INVALUABLE AND INDISPENSABLE. THEY ARE SOFT, LIGHT, ANTISEPTIC, AND ARE SUPPLIED AT THE ACTUAL COST OF WASHING. AFTER USE THEY ARE SIMPLY BURNT.

Carriage Paid to the Medical Profession only. Samples free on application.

Sample Packets of 1 dozen at 2/-, 1/4, 1/-, and -/6, post free; or 12 Packets at 19/6, 13/6, 9/6, and 5/6.

ACCOUCHEURS WILL FIND IT A GREAT COMFORT TO THEIR PATIENTS BY USING

HARTMANN'S SANITARY WOOD WOOL SHEETS

For Accouchement, Bedsores, Operations, &c.

PERFECTLY ANTISEPTIC, CLEAN, & COMFORTABLE,

The most comfortable Appliance for Accouchement ever made. "Risk of Puerperal Fever diminished."

A Great Boon for Patient, Nurse, and Physician in attendance.

Used in the Principal Lying-in Hospitals of London, Manchester, Edinburgh, Glasgow, &c.

These Sheets are made of Hartmann's Patent Wood Wool Wadding, the most absorbent substance ever known. They are most comfortable and healthy, are perfectly antiseptic, have not the disagreeable smell so common to indiarubber sheets, and are much cheaper. In Accouchement a large sheet is laid under the patient, it absorbs the discharge completely, and is SIMPLY BURNT after use. No soiled clothes; risk of puerperal fever greatly lessened; and perfect comfort and cleanliness.

Prices of the Three Sizes - - 1/-, 1/6, and 2/6.

Sizes: 24 by 18 in., 26 by 20 in., 32 by 32 in.

Reduced Prices to Doctors and Nurses.

The SANITARY WOOD WOOL COMPANY, Limited,

26, Thavies Inn, Holborn Circus, London, E.C. *Telegraphic Address*—"LIGATURE, LONDON."

An Address

ON

THE DEVELOPMENT OF LONDON HOSPITALS DURING THE NINETEENTH CENTURY.

Delivered at the Portman Rooms on Nov. 4th, 1898,

BY CLINTON T. DENT, F.R.C.S. ENG.,
SURGEON TO ST. GEORGE'S HOSPITAL.

THREE EPOCHS OF DEVELOPMENT.

THE development of London hospitals, the changes which have been brought about in their working, their administration, and to some extent their aims, and the improvements which they have undergone have shown, as might be expected, a fairly constant rate of progress during the century; but there have been certainly two, and possibly three, epochs when the development has been very marked. As instances of this I may cite the early part of this century, when efforts began to be directed to the improvement of sanitation; to the years following the Crimean War, when the change of ideas with regard to hospital construction, ventilation, &c., was not less remarkable than the simultaneous development of the art of nursing; and, lastly, the period when the practical application of the science of biology and the introduction of the antiseptic system began to make themselves felt. It is not my intention to dwell too long on the past. Antiquarian research is profoundly attractive to the searcher, but the unearthed results lose much of their interest when set out ticketed and captive on museum shelves. Yet unless we can form some picture of the hospital of 100 years ago we have no material for comparison.

I need only give an outline sketch of London hospitals as they were at the close of the last century and I will limit myself to the principal large general hospitals of London. With lunatic asylums, even when called hospitals, I am not now concerned. I have collected information about some seven of the older London hospitals, and in what I have to say about them at the close of the last and the beginning of the present century I shall seek rather to draw a general picture — every detail of which is to the best of my knowledge accurate; but I shall not endeavour to reproduce, as it were, a photograph of any one in particular. Nor need I specify them. Each hospital had its own individual features then as now (and it is, in passing, distinctly to the interests of the public that such should be the case), but the general standard of the leading hospitals was probably much the same in all. Nor shall I make allusion to the numerous, and often unnecessary, small hospitals which then, it may be, as now, existed. I may ignore institutions run for the gratification of a particular fad or the advertisement of a particular faddist, or worked ostensibly for the benefit of the deserving poor, the promoter being sometimes the poor person whose case, in his own estimation, was the most deserving. Probably institutions of the kind were always to be found, but I am not now concerned with hospitals which were only such in name and not in real object. They may have filled their temporary purposes and vanished. It matters not. If they have disappeared let them have but the epitaph which the poet suggested for himself—

> "Unknown, unhonoured, let them die,
> And let no stone mark where they lie!"

CONSTRUCTION AND FITTINGS OF A HOSPITAL 100 YEARS AGO.

In construction the hospital of 100 years ago was of course inferior, as we should judge, to the standard of to-day. Yet the buildings were, as a rule, planned according to the most enlightened views of the moment. In one or two instances, however, an attempt was made to convert buildings designed as houses into hospitals, an experiment which is always unsatisfactory and invariably expensive. The ground plan was usually of the type still frequently adopted. The building was either enclosed like many of the colleges at our universities, or laid out in the shape of a capital letter E or T or H. The separate block system—excellent where there is much space available and a large income—was an innovation of recent date. The windows would seem small to us now, but compared with the prevailing architecture appeared unusually numerous and large. Much, I may mention at once, of my information is derived from the writings of John Howard. The excellence of his philanthropic work with regard to prisons is well known. But his work in connexion with hospitals is quite as good and shows him equally to be many years in advance of his time as a sanitarian. And he set down in writing only what he saw. Within the building the first thing that would have struck the modern beholder would probably have been the rough wooden passages, landings, and staircases, for we live now, architecturally, in an iron and stone age. John Howard in 1789 notes that the staircases in almost all our hospitals are of wood and adds: "The stone staircases in hospitals abroad are more proper." The corridors were often—in fact, usually—narrow and dark. At one large hospital it was noted that they were 8 ft. wide. The windows were sometimes on both sides of the ward, frequently only in one, and in the latter case there was not always even corridor ventilation. The air in much of the ward was therefore stagnant. The wards themselves were commonly poorly lighted and decidedly crowded. The male and female wards were often on the same side of the house. Medical and surgical patients were in some instances mixed in the same ward. As a rule the wards were very low, in one hospital being only 9½ ft. in height; 20 ft. was an average width. Sometimes, however, they were lofty, perhaps 12 ft. or 14 ft. in height. The walls were whitewashed, when they *were* whitewashed, for often they appear to have been exceedingly in want of that process. The floors were often sanded. In a somewhat rare print representing a ward in one large general hospital eleven beds are shown arranged along the wall and five windows are shown. Some of the wards in this hospital contained thirty beds. In the general wards there appears to have been a fair amount of ventilation and the windows were generally kept open, especially on the women's side. Frequently, however, the lower sashes of the windows alone were constructed to open, and sometimes the upper sashes were so cumbersome and heavy that they could not be moved without trouble, so that it is pretty safe to assume that they were more often closed than open. In one hospital the windows of one of the men's wards situated on the ground floor opened inconveniently low down close to a main thoroughfare. It was brought to the knowledge of the governors of this hospital that the friends of patients were in the habit of passing in victuals and drink from the road into the ward. With a laudable desire to put an end to this dangerous practice the governors took the practical step of ordering the lower sashes to be fastened down. They thus substituted for the dangers of insobriety the perils of asphyxia, for it is not very clear how, after the order was executed, any ventilation at all was provided. But at one hospital which was rebuilding gradually at the end of the last century the new wards were "very large and lofty" and free ventilation was secured. Moreover, ventilating openings were provided to communicate with the chimney—a method which, re-invented within the last few years, has now again fallen into disfavour. The bedsteads were usually wooden and almost invariably provided with testers, that is to say, they were fourposters with a square canopy on the top, and in addition generally pretty closely curtained up. Sometimes, as one print shows, they were built right along the wall, forming a series of boxes like cubicles. It could have been no easy matter, therefore, to get to both sides of the bed and in order to reach the windows it was necessary apparently to climb over the beds. The mattresses were usually of straw. John Howard noted with approval that in some cases hair mattresses had been recently introduced. The beds were so arranged that the occupants lay parallel to the wall, and in the print which I have mentioned no space is shown between the beds, perhaps to economise the woodwork. The defects of these wooden bedsteads did not pass without comment. Thus, Samuel Sharp, a surgeon to Guy's Hospital, in the course of a journey to Italy about 1765, noticed with approval in Florence an iron-framed bedstead, and he mentions that attempts to make similar bedsteads in England had failed. The ingenuity of the ironworkers improved or prejudice was slowly overcome, for some forty years later iron bedsteads began to be introduced. Sharp makes an observation on another subject which, though unpleasant, we cannot pass by

Digitized by Google

and may dismiss by merely quoting what he says. Speaking approvingly of the iron bedstead he argues for its adoption on another ground and tells us (I quote his words), "that in the hospitals at London bugs are frequently a greater evil to the patient than the malady for which he seeks a hospital, and could I have interest enough with the governors to bring about an imitation of this frame I should be exceedingly rejoiced in the comfort it would afford to so many thousands of miserable wretches as are tormented sometimes even to death by these noxious vermin." This statement is strong, but there is abundant evidence to show that it is little exaggerated.

SPECIAL WARDS.

In all hospitals of that date, and for long after, there existed what were known as "foul" wards. The object of these wards was the segregation of particular classes of diseases and the arrangement was not enforced solely on medical grounds. The epithet applied really to the disorders of the patients, but the common supposition that it referred to the ward was not without justification, for in these rooms the ventilation seems to have been more defective than elsewhere. Thus Howard notes when on a visit to one large hospital that in none of the four foul wards for men was a single window open, and at another, in which the other wards are described as fresh and clean: "There were three foul wards in which were 53 men and 27 women and there was no window open."

The extent to which, in a general hospital, patients suffering from different disorders should be treated in a common ward and the extent to which they should be classified according to their complaints and treated in special wards is a question of the day. At present there is a strong tendency to classify; this is the outcome of the modern craze for specialism in medicine. For instance, erysipelas wards—perilously akin to the old "foul" wards—were common a very few years ago. But now that disorder happily occurs rarely and is met by isolation rooms. But the advisability of treating typhoid fever in general wards is a question of the moment, while it is possible that our paulo-post-future successors will marvel at the principles we adopt now in dealing with that scourge of civilised communities—tubercle.

VENTILATION AND SANITATION.

To return from this digression. It was owing, I think, in great measure to John Howard's crusade that improvements in structure, ventilation, and cleanliness in hospitals were gradually effected. The managing authorities were at all times keenly alive to the necessity of providing air, light, and improved sanitation, but were hampered constantly by want of funds.

With regard to the underground sanitary system there is not much to be said—for somewhat obvious reasons. A century ago people if not tolerant of nuisances crying aloud in their midst were at any rate extremely slow to remedy or do away with them. It is not much more than a hundred years ago that the pestilential Fleet Ditch was finally arched over and ceased at length, in Pope's words, to "roll its large tribute of dead dogs to Thames" under the very eyes—and noses—of Londoners. We learn of other imperfections in hospitals from John Howard's observations. He remarks that the water-supply was not particularly abundant and notes in 1790 with much admiration that one hospital then in process of rebuilding had a free supply of water to its lavatories, this arrangement being evidently a rare exception and innovation. There was no great supply of baths. In one hospital Howard notes that in a dirty room in the cellar was a hot and cold bath, which seemed to be seldom used. In another hospital with over 400 patients there was a large cold bath and a room adjoining for a warm bath. In another there were excellent baths in clean and neat rooms, while yet another had a good cold bath, but not used. The conditions, then, to modern ideas seem unfavourable enough, but it was in institutions such as these, assisted by the very imperfectly skilled but often most devoted nursing, that men like John Hunter, Astley Cooper, Benjamin Brodie, and others worked, and not only worked but succeeded.

I may seem to have drawn an unduly dark picture of the old hospitals in the vital matters of ventilation and sanitation. That they were not perfect from the sanitary point of view then must be admitted. I trust that we shall not hinder progress by assuming that they are perfect now. But beyond all doubt hospitals then, as now, were infinitely in advance of other institutions and dwelling houses. Let me quote a passage from a recently published book in support of my assertion. The author of "Collections and Recollections," speaking of the development of humanitarianism, points out that this was evidenced to the eye by the changes in domestic architecture. He writes: "There was less pretension in exteriors and elevations, but more regard to convenience and propriety within. The space was not all sacrificed to reception-rooms. Bedrooms were multiplied and enlarged, and fireplaces were introduced into every room, transforming the arctic 'powdering-closet' into a habitable dressing-room. The diminution of the window tax made light and ventilation possible. Personal cleanliness became fashionable and the means of obtaining it were cultivated. The whole art or science of domestic sanitation—rudimentary enough in its beginnings—belongs to this century. The system which went before it was too primitively abominable to bear elaborate description. Sir Robert Rawlinson, the sanitary expert who was called in to inspect Windsor Castle after the Prince Consort's death (1861), reported that within the Queen's reign 'cesspools full of putrid refuse and drains of the worst description existed beneath the basements. ..... Twenty of these cesspools were removed from the upper ward and twenty-eight from the middle and lower wards. ..... Means of ventilation by windows in Windsor Castle were very defective. Even in Royal apartments the upper portions of the windows were fixed. Lower casements alone could be opened, so that by far the largest amount of air spaces in the rooms contained vitiated air, comparatively stagnant.'" Public opinion in these matters pursued its usual course. People for long—for the best part of a century, in fact—remained indifferent even where they felt something was wrong. The voices of the preachers of science were heard crying persistently that the "sanity of sanities was sanitation," but they were disregarded. Then the usual thing happened; of a sudden public opinion exploded and people said that these defects were abominable, disgraceful, and scandalous, never ought to have been, and should instantly be remedied. There was a mighty stir and the movement affected hospitals also, but these institutions, already far in advance, had no difficulty in maintaining their position and still leading the way. The old superstition—it is no more—that hospital air is necessarily foul is pretty well exploded now. You have but to look to results to recognise that from the first, as now, it was a libel. Still, the improvement in sanitation constitutes one of the greatest features of hospital development during the century.

RECENT IMPROVEMENT IN HOSPITAL MANAGEMENT.

The second great impulse followed shortly after the Crimean War. Public opinion had been roused by the horrors incidental to crowded hospitals. The result in home hospitals was a tremendous outcry for space and light in wards. Cubic capacity was everything for the time till really it seemed as if an ideal type of hospital building would have been a kind of Crystal Palace. Opinion has since toned down on these points and now the tendency is rather to look upon area of floor space as a most important point. A still further and great impulse was given to details of hospital construction within quite recent years by the introduction of the antiseptic system, perhaps the most beneficial and far-reaching discovery of the present century. Like many another great discovery—like most, in fact—others had had a vague inkling of it. A study of history always reveals men in advance of their time, whose minds seem almost inspired with prophetic gifts—men, for instance, like Dr. William Budd of Bristol or Edward Jenner, of the colossal value of whose discovery of vaccination the "conscientious objector" will in a few years convince all men. But the whole credit of the antiseptic system is, of course, to be assigned to the man—Lord Lister—who, focussing the work of others and supplementing it by his own, forced mankind to recognise its full value.

On many details which might be of interest I have no time to touch. In every department progress, though often slow, was decided. The domestic administration of hospitals reflected the customs of the time. Thus, in old days the diet of the patients was much the same as now. The allowance of meat was large; cheese was commonly included. In some hospitals, Howard notes, the allowance of vegetables was very scanty. As might be expected, stimulants were given rather freely. The quantity of beer allowed was

Digitized by Google

curiously large, three pints being almost the usual quantity in summer and two pints in winter. The beer is usually described as "small," and no doubt justified its title fully. There was constant trouble with regard to the illicit introduction of stimulants, and the resident staff, nurses, and others in the hospitals of former days seemed to require a good deal to sustain them in their arduous duties. Howard speaks with not unmerited disapproval of the common practice that obtained of bringing great quantities of beer into hospitals. Moreover, at some, as he ascertained, the patients could easily get out, there being no proper attention to the gate, so that "the adjoining ginshop often prevented the efficacy of medicine and diet." It was no uncommon thing—it was, in fact, almost a common practice—for the potman to go his rounds of the ward like a medical officer might in the present day.

NURSING.

To the subject of nursing in hospitals I can only briefly allude. Nursing generally has attracted so much attention of late that some may regard it as almost a new adjunct to hospital treatment. This is, however, far from being the case. Sir James Paget, speaking from hospital experience of about the first fifty years of the Queen's reign, remarks that "in the nursing department the happiest changes of all have come about." True enough; but the passage signifies development, not a new departure. It must be remembered that the, so to speak, original nurses were members of religious orders. I date back to the time of St. Vincent de Paule and the Foundation of the "Gray Sisters." These women were bound by vows and were prompted by motives of mortification and penance to engage in work at once philanthropic and a little degrading. But without arguing as to motives they were unquestionably animated by a very high ideal; and I could sometimes wish that this same spirit were more common than it is now. Gradually these nursing sisters departed from their fine traditions. There is overwhelming evidence to show that the original nursing sisterhoods in their zeal were too often inclined to care for more than the bodily welfare of their patients. And so it came to pass that the nursing of the sisterhoods fell into disrepute. They were succeeded by an inferior class. At the beginning and even in the middle of this century nursing was still considered a menial occupation. Still, in every hospital many high-class nurses were to be found devoted to their work and fully abreast of the knowledge of their time. They had not the scientific acquirements of the nurse of to-day, neither had the sanitarian or the medical man. A great change during the century has been the recognition of nursing as a profession, and a fine one; the training and education of nurses as nurses from the beginning of their career, their relegation from the outset to true nursing duties and their separation from the ranks of ward maids, scullery maids, and scrubbers. It is in the all-round standard of hospital nursing that the change is so marked and not so much in the individual excellence of matrons and sisters. As medical knowledge advances scientific nursing should advance too, and I trust that each will develop on its own true lines.

THE DISCIPLINE OF PATIENTS.

The general tone and discipline of hospitals are matters I must allude to, as they bear on the conclusions towards which I have been working all along. In the early part—say, the first quarter—of the century discipline was evidently lax in some respects, but it was unduly stringent in others. A hospital a hundred years ago would scarcely have dared to enforce a curious old ordinance which I find once existed. The porter, whose duty was also to see that the male patients said the appointed prayers of this hospital, had the following instruction: "And whatsoever poor person shall be found a swearer or an unreverent user of his mouth towards God or His holy name, or a contemner of the Matron, or other officer of this house, or that shall refuse to go to bed at the lawfull houres before appointed, him shall ye punish (after once warning given) in the stocks." But though such forcible methods of ensuring discipline would have been out of the question a century ago the spirit which dictated them still prevailed. Hospital patients when able were almost universally required to assist in the work. This is the case no longer. The inmates formerly were kept tightly in hand and never allowed to forget for a moment that they were the recipients of charity, that hospital relief was a favour rendered possible by the benevolence of others, and that for benefits gained they were indebted not only to the medical man who treated them, the sister who nursed them, but also, and chiefly, to the managing authorities representing the subscribers who provided and maintained the institution. I will not trace the change. I do not use here the word improvement. Just consider hospitals as you see them to-day. The contrast is astounding. And those of you who know hospitals and have studied their history will agree with me that no feature in hospital development during the century is so remarkable as the change of relation between the hospital and the public and the fundamentally different view-point from which the public and the hospital patient class have come to regard the hospitals. Many causes have contributed to this—all, in fact, which I have hitherto dealt with.

THE RISE OF HOSPITAL ABUSE.

The old and more stringent laws of discipline were only possible when the hospital patient class was well defined and limited to the very poor. There is good reason to suppose that hospitals in the early part of this century were, on the whole, utilised by the class for whom they were originally intended—that is, the poor and the very poor. There are not wanting indications that the managing authorities were always quite alive to the possibility of abuse. Thus in an old ordinance printed in 1652 of one hospital it is laid down as an order of the hospital to the "chirurgians" "that we utterly forbid and command you that ye by no coloure, pester, or burden this house with any sick or diseased person, for the curing of which person ye before have received a sum or sums of money, upon paine to be dismissed this house." The best guarantee, however, that the comparatively well-to-do did not seek relief in hospitals lay in the fact that these institutions not being much known were rather held in dread. We are not concerned with the kind of ailments which enabled a poor person to gain admission to a hospital. For the most part they must have been much the same as they are now. One London hospital reserved a certain number of beds—14 out of 71—for incurable cases. In Bowles's print of Guy's Hospital, dated 1725, a scroll across the sky bears the inscription "Guy's Hospital for Incurables"; but Guy in his will made it abundantly plain that he desired the benefits of the institution to be given to those whose ailments admitted either of relief or cure, and it does not appear that at any time cases such as we should now class as incurable were admitted. They had to seek relief, as is very right and proper, from the parish or the State and were not considered fit objects for private benevolence. In the same way in another of the old ordinances of St. Bartholomew's Hospital the "chirurgians" were directed to "signify to the almoners or hospitalers their judgment of the diseased person brought before them and to signify without all affection whether he or she be curable or not, to the intent there may be none admitted into this house that shall be incurable to the great let and hindrance of the curing and helping of many another, nay, none rejected and put back that are curable to the great slander of this house and the displeasure of God." A previous passage refers to the poor of this hospital and the "chirurgians" were directed "to show equal attention to the poorest, destitute of all friends and succours, setting aside all favour, affection, gain, or lucre." The letter of such ordinances might read differently in these days but the spirit has prevailed and should prevail. At most hospitals the patients made payment, that is, the part payment system was in early days enforced. Some, however, from the very first accepted no sort or kind of fee, reward, gratuity, or payment, and to their great credit refused to alter their rules even when in very low water financially, preferring to close some of their wards rather than abandon any of their principles. At one hospital the "parish poor and soldiers" had to pay 4*d.* per day for their subsistence. At another fees were taken for the admission of patients. For clean patients, 2*s.*—viz., 1*s.* for the sister, 6*d.* for the nurse, and 6*d.* for the beadle. For foul patients, £1 5*s.* 8*d.*—that is to say, 5*s.* for flannels, 18*s.* 8*d.* for two months' subsistence at 4*d.* per day, and 2*s.* for "ward dues." At another hospital every clean patient had to pay 3*s.* 6*d.* on admission and a "foul" patient 10*s.* 6*d.*, besides 4*d.* a day. These latter patients had also to pay the nurses for washing their linen. Howard notes that at another hospital he saw a woman bring a child and "with tears leave the fee of 2*s.* 9*d.* for the nurse and 6*d.* for the steward." The foul patients

Digitized by Google

for this hospital paid 7s. This part-pay system was gradually dropped entirely, and the methods which some hospitals adopted from the outset of exacting no payment whatever and of holding that anybody capable of paying was thereby disqualified for admission became general. Lack of funds, however, within recent times has again caused the payment system to come into vogue to a limited extent, though on a different kind of footing. But it shows happily signs now of soon coming to an end in all general hospitals. Of course, many cases that would, a hundred or fifty years ago, have been legitimately classed as "incurable" would now no longer fall into that category, for with the advance of medicine and surgery many who would previously have been deemed hopeless can be now, if not set on the high road to recovery, at least materially relieved. This diminution of the cases formerly deemed incurable has of course largely added to the number of eligible cases, and the fact may as well be faced at once that the number is likely to increase. It would be true and easy of proof to contend that the beneficent work of hospitals has enormously increased during the century, and that they are highly efficient now; but this would be a cheap boast. We may hug ourselves with the comfortable conviction that things now are better than they were formerly. A certain Pharisee adopted this attitude of mind and was not highly commended for so doing. It is as unquestionable that improvement and progress have been made as it is certain that the final point has not been nearly reached and that a future generation will far surpass the standard of to-day. The point I wish to repeat and emphasise is that the improvement has brought reputation to hospitals which formerly they lacked. If people did not criticise hospitals so much in old days it was only because they paid less attention to them. Hospital patients in very early times were almost cut off from mankind, as if they were lepers, and, indeed, mediæval hospitals were as much founded for the protection of the sound as for the relief of the sick. They were, in fact, regarded much as we regard hospitals for infectious diseases now. Gradually and during the present century all this has altered. Hospitals have become better known, and the public generally, as well as the beneficent and charitable, who support them have begun to take an interest in their medical and social aspect. People became aware that patients in hospitals were not all suffering from highly contagious and infectious disorders, so that it was positively dangerous to go into such institutions. Such ideas, of course, only arose from ignorance of these places, but they were none the less widely entertained. The establishment of infectious hospitals and the better understanding of infectious disorders again improved vastly the general reputation of hospitals. But it all comes in short to this—the better you build, ventilate, and drain, the better you officer and nurse, the more you modify regulations in the direction of placing the patient who pays nothing and costs much in the same position as the patient who pays more than he costs—the more you pursue these lines the more you drive the benevolence of the supporters into the background from the hospital patient's point of view and the more you encourage the feeling of prescriptive right to hospital treatment. And from these causes, too, it has gradually come about, as I have been trying throughout to indicate, that during the century hospitals, whether founded and supported by the voluntary subscriptions of the charitably disposed or by the munificent endowment of private individuals, have become public institutions. I think this fact is too apt to be overlooked. I offer no opinion as to whether this state of things is matter for approval or regret. I only desire to draw your attention to matters as they are.

PROPOSALS FOR HOSPITAL REFORM.

The increased reputation of, or, if you prefer the phrase, the increased interest taken in, hospitals gradually brought into prominence the alleged existence of evils, rather vaguely designated under the generic title of "hospital abuse," that it is stated have grown, are growing, and ought to be diminished. The results of the inquiry of the Select Committee of the House of Lords in 1892 are probably fresh in your minds. The practical conclusion set forth in that most admirable though almost too impartial report amounts broadly to an admission that some "abuses" did exist, but to a far less extent than had been alleged. Recently there has been much talk of hospital reform, though hitherto very little action. Many proposals have been put forward for modifying and altering the work and the administration of hospitals. Some of these are quite outside my scope and I can only just mention them. Of one you have already heard here—the proposal for a Central Hospital Board. The idea is a good one, but there are two great difficulties to be overcome before it can be called into existence. One of these difficulties is the representation, and the second is that the board, however well constituted, could do little effective work unless it had the command of adequate funds. Another proposal of a much more sweeping character is to nationalise or municipalise hospitals, throw their expenses, that is to say, on the taxpayers or the ratepayers. This is a subject not for the end of one lecture but for a course of several lectures. The change may come, but it seems as yet happily far off, and when I point out to you that if the rates or the State take over hospitals they must perforce take over medical education also you may recognise that the question is not to be approached without due consideration. Possibly the first step may be to recognise that hospitals have gradually become public institutions. The granting of subsidies from the State is a method which finds little favour in this country. And the system which obtains in France of recognising particular institutions as of "public utility" is not adopted. The position of our hospitals really is that they are "recognised as of public utility" and have to bear the responsibility attached to that position, but that they do not get the consequent grant. The much-needed subsidy has again to be supplied by individual effort and by charitable appeals. The Hospital Sunday Fund and the Prince of Wales's Fund are attempts to do what some think the State should do, and not a few think the State will have to do before a great many years. The present subsidising bodies exercise only a very limited control. A State subsidy would mean some degree of State control, though possibly leaving intact to a great extent the individuality of the different hospitals. On this ground the Select Committee did not report in favour of the plan. Through the State alone I believe will it be found possible to institute and maintain a really efficient Central Hospital Board with sufficient power to exercise the necessary control and sufficient permanence to ensure good working. At the same time, let me express my conviction again that I believe, as strongly as I hope, that such solution of the difficulty is yet far distant. I only hope so, for as far as I have studied the question I feel assured that State or rate hospitals would be less efficient than the present institutions and would cost from three to five times as much. The day may come for this change, but when it does it will not be for the good of the poor. It will diminish the efficiency of hospitals, damage seriously medical education, and benefit only the hospital medical staff who will flatly refuse to work any longer without adequate payment.

THE OUT-PATIENT QUESTION.

I may only touch on one other subject of hospital reform—namely, out-patients. Let me state at once my own conviction that an out-patient department at general hospitals is essential in the interests of the poor and in the interests of medical education. Now it must be borne in mind that the out-patient system has grown up during the present century. At my own hospital—St. George's—they seem to have begun as we know them now about sixty years ago. The assistant physician and assistant surgeon of to-day are mainly concerned with out-patients. But this was not the case a hundred years ago. At St. George's Hospital we had no assistant physician till 1830, and the assistant surgeons were really appointed as assistants to the surgeons when the latter applied for such help. Patients who had been in the hospital often attended for a time after their discharge, but such were obviously on a wholly different footing. Mr. Loch, who has inquired closely into this point, finds the first mention of out-patients in 1564 at St. Bartholomew's Hospital. The physicians then had 8 under their care. In 1749—nearly 200 years later—the number had increased to 200. I believe that these were not out-patients in the modern sense but principally in-patients who had been discharged and whose progress was being watched and to whom some treatment was allowed.

Now there is no doubt at all that the number of out-patients at hospitals has increased very largely of late. Under the heading of "out-patients" are generally included in statistical returns what are known as casualties, and it is especially in the list of casualties that the numbers have swollen. Thus I find by a published return at one hospital

Digitized by Google

that the number of out-patients is almost exactly ten times as great as it was sixty years previously. It is stated that the number of patients properly qualified for hospital relief is not increased in anything like the same proportion, and that many must therefore be seen at hospitals who, according to the original intentions of the founders, would have been deemed ineligible. It is asserted, too, that this relief is almost indiscriminate and that the ease with which a person can obtain gratuitous treatment with little or no inquiry has the twofold effect of pauperising the applicants and depriving the practitioner of his means of livelihood. As to the extent of this "abuse" I will only say this—that I am as convinced that some exists as I am certain that its amount is greatly exaggerated. I have endeavoured to suggest that the increased efficiency and the improved repute of hospitals accounts for the increase of the work they try to achieve. While this is matter for congratulation we must at the same time face the altered condition of affairs. If any "abuse" at all exists it ought to be checked, and even if there is no abuse preventive measures to guard against its occurrence are none the less desirable in the interests of the hospitals, of the public, and of a large, hard-working, and most deserving body of men whose cry is bitter and not without justification—I refer to the general practitioners whose work lies among the poor.

Limitation of the number of out-patients is a reform of a much larger character than people who are not conversant with hospital statistics might suppose. The system of limitation has stood well the test of experience. If generally adopted by London hospitals the beneficial effect would be marked and far-reaching. There are signs that the principle of limitation is becoming more widely accepted, and I have little doubt that if a Central Hospital Board could be constituted in which all the leading hospitals were represented the question would be one of the first to be discussed and probably settled. The individuality of different hospitals is a great advantage, but this need not be carried to the length of preventing joint action altogether in a matter of public importance.

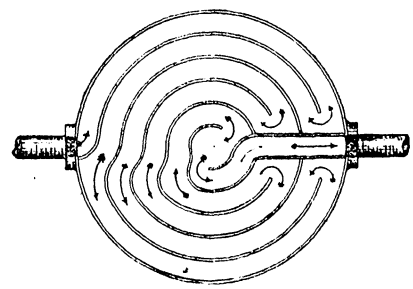
In Conclusion.

Of other minor "reforms" which have been recently advocated I have left no time to speak. Some interesting suggestions have been put forward in a scheme of the Belgrave Hospital for Children, recently published and commented on in THE LANCET of April 30th, 1898. The principle underlying many of these proposals is the recognition of the general practitioner as one whose interests may be affected prejudicially by hospitals and whose claims to consideration are therefore admitted. The scheme is novel and as it is meeting with support more is likely to be heard of it.

I have alluded to many changes, but in one all-important respect there is little or none to record. All the hospitals which I have had in mind were founded on benevolent, judicious, and enlightened general principles, and these, crystallising gradually into traditions, have been faithfully carried out by those responsible for their management and government.

BRIGHTON AND SUSSEX THROAT AND EAR HOSPITAL.—The new building in Church-street, Queen's-road, Brighton, will be publicly opened by the Duke of Norfolk on Tuesday, Nov. 29th, at 12 o'clock. The building, which has been erected at a cost of £4600, will accommodate 20 in-patients, besides having a convenient out-patient department.

THE PLAGUE.—The latest telegraphic intelligence from India is not by any means satisfactory. The epidemic continues to prevail in Bombay city and district, at Karachi, and at Bangalore. Six districts of the Madras Presidency are also infected as well as some other stations. The Government of India have asked for more medical aid to be sent out for plague duty in the Madras Presidency.—— News has been received from St. Petersburg of a very severe outbreak of plague at the village of Kischlah, in Central Asia; out of a population of 350 there have been 225 deaths. The Duke of Oldenburg, president of the Government Commission which has been appointed by the Emperor to devise means for arresting the propagation of the plague, was expected at Samarkand with eighteen doctors and officers of health and fifteen Sisters of Charity, as well as four cooks. It will be the first time that a member of the Imperial family has visited Turkestan.



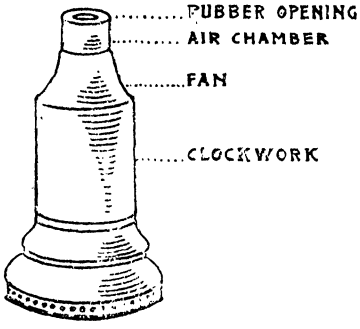
ON THE TREATMENT OF NEURALGIA AND RHEUMATISM BY CURRENTS OF HOT AIR, WITH SOME ACCOUNT OF THE APPARATUS EMPLOYED.

BY WILLIAM TAYLOR, M.D., F.R.C.P. EDIN.

ONE of the most obstinate cases of rheumatism I ever had to treat was contracted by a patient whose writing-table was in close proximity to a window in his counting-house. There he sat and suffered without ever suspecting that a slight draught from that window was the immediate cause of his trouble. It did not create that trouble, for its foundation was in his rheumatic constitution, and the keenness with which he entered into his business affairs made him forgetful of cold feet and a certain chilliness of the arm and knee nearest the window. It was only the consequent illness that awakened his recollection. This is but one example of what must meet the experience of every member of our profession from day to day, and the very mention of it must recall numerous instances of less obstinate but more painful affections, classed under the general term of neuralgia, which owe their existence to an equally slight and far more transient exposure. A consideration of such cases and their apparent causation suggested to me that the application of a current of hot or warm air might perhaps have the opposite effect to that which I believed to be produced by a current of cold air. The difficulty which met me and which I set myself to solve was how to obtain such a current. I found that air, although easily warmed, is very rapidly cooled, so that it cannot be carried far from the source of its heat, that the degree of temperature is difficult to regulate so as to keep it within extremes, and that to confine its action within definite limits so as to act on and not beyond a prescribed area is no easy task.

My first device consisted of a flattened coil of brass tubing bound together and placed over the flame of a Swedish "Primus" lamp. Through this coil by means of bellows a current of air was forced which became heated in transit and emerged hot at the free end. The tubing was difficult to coil and the process employed was tedious and expensive. It was superseded by a hollow casting made from a design suggested by the plan of the "walls of Troy" (Fig. 1). It

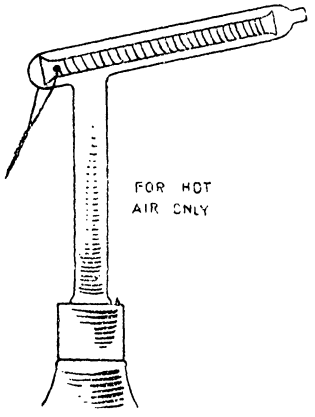
FIG. 1.



is circular in shape and the interior is subdivided into a tortuous channel in traversing which the air becomes heated and emerges directly from the hottest part at the centre. I employed this with benefit in an obstinate case of torticollis and in recent rheumatism of the knee-joints. It may still be useful in such cases, but it is not suitable for the treatment of pain affecting limited areas such as have to be dealt with in facial neuralgias. It is very heavy, not difficult to heat, but when heated dangerous to handle. The blowing of the bellows is very tiresome and the heat and fumes from the lamp become very disagreeable. These inconveniences have been remedied by the substitution of glass for brass, a rotatory fan for the bellows, and electric heat for the offensive lamp. In the attainment of these improvements I have to acknowledge the invaluable assistance of my friend Dr. Milne Murray.

The apparatus which I next devised and which I now use is composed of two parts—one of metal and the other of

Digitized by Google



glass (Fig. 2). The metallic portion consists of a shell containing a rotatory fan, the clockwork or electro-motor which actuates it, and a small air chamber above the fan, which is perforated on the top by a rubber-lined orifice adapted for

FIG. 2.

the reception of the glass portion of the apparatus (Fig 3). This consists of two tubes, one within the other. The lower end of the outer tube is inserted into the opening on the top of the air chamber, the other end is free. It may be straight, or fashioned into a variety of shapes, and may or may not terminate in a contracted nozzle. Close to the free end there may be an expansion for the reception

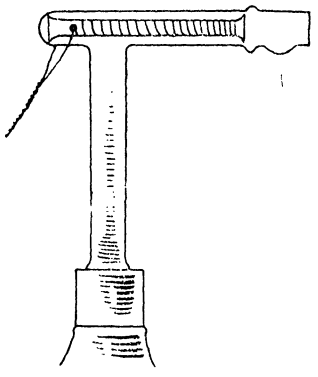


FIG. 3.

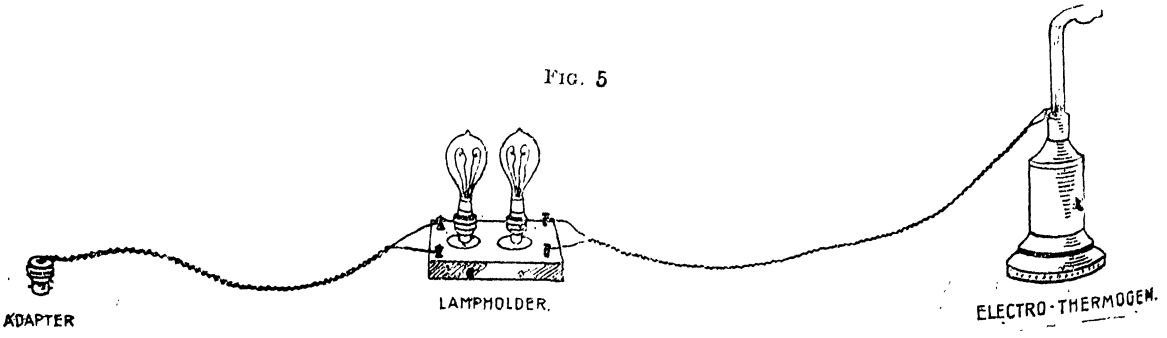
of volatile substances for use as inhalants or as auxiliaries in the treatment of localised pain (Fig. 4). Such medicaments are inserted by means of a suitable pipette into the expanded portion and are speedily volatilised by the hot current passing over them. The inner tube is wound round with a spiral of fine wire, the ends of which are connected with terminals fixed in the outer tube. To these terminals are attached insulated conducting wires, by means of which a current of electricity is conveyed through the spiral of sufficient strength to heat it. The fan revolves at a rapid rate and sends through the tubes a current of air which in its transit becomes heated and leaves the mouth of the outer tube in a condition suitable for direct application to the affected part. Intermediate between the source of electricity and this apparatus is placed a lamp-holder supplied with lamps of such calibre as to interpose a suitable resistance to the electric current. By means of these the temperature of the heated air can be suitably regulated. (If the voltage be from 100 to 130, as in many parts of London, two 16 candle lamps may be introduced into the circuit. If the voltage be 230, as in Edinburgh, two 32 candle lamps may be used.)

The lamp-holder (Fig. 5) has four terminals. Two of these at one end communicate through conducting wires with the terminals of the coiled wire, the other two are attached to a length of similar wire which terminates in an adapter suited for fixing into the socket used for holding the stem of

FIG. 4.



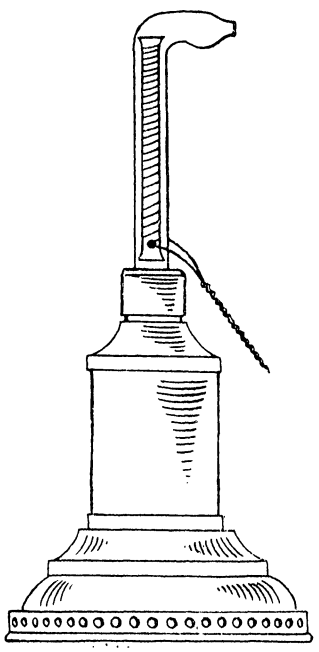
an ordinary incandescent electric lamp. The name which has been suggested to me for the apparatus is the electro-thermogen (Fig. 6).

When all the attachments are completed as above, and not till then, one of the house lamps in any convenient place should be removed from its socket and the adapter inserted in its place. This done, the lamp in the lamp-holder will immediately glow provided that there is no defect in the connexions (if the lamps do not glow the adapter should be removed from the lamp socket *before* the connexions are examined). The clockwork should then be wound up fully and the hot-air current will begin to flow.

I do not know to what degree of heat the temperature of the air can be raised by the electro-thermogen. I tested it with my own thermometer and found that it rose rapidly until it reached 212°. It rose even higher, for in a few moments it burst the bulb. This satisfied me as to its capabilities.

We are told that in the Arctic regions, where the air is still, persons can endure a far lower temperature than where the air is in motion, so that the effect experienced is not regulated so much by the degree of cold as by the successive impinging of cold particles upon the surface, say, by the action of a gentle breeze. Hence the detrimental effects of a slight draught. With heat a similar rule holds good. In a still temperature of 260° a beef-steak can be cooked in 33 minutes, but if air of the same temperature be blown upon the meat by bellows it can be cooked in 13 minutes. In accordance with these facts I have found that in treating neuralgia a moderate current long continued is far more effective than a more intense current of short duration. The almost invariable remark of patients when so treated is,

FIG. 5



Digitized by Google

"That is very soothing," and no more welcome observation could be made, for anything that is to benefit one suffering from neuralgia must be of a soothing nature.

In applying this treatment for certain cases of persistent long-continued neuralgia I have been struck with the existence of thermal anæsthesia in the affected areas. These patients do not feel either the soothing or burning effect of the hot-air current. In one case, that of a woman aged twenty-two years, who had suffered from neuralgia for thirteen months in a spot 1 in. distant from, and in line with, the left eyebrow, this anæsthetic condition was present. On applying the hot-air current I was surprised to find that she made no remark. I increased the temperature but still she did not seem to feel it, although the adjacent parts were sensitive. By-and-by the surface of the affected part became blanched, and I told

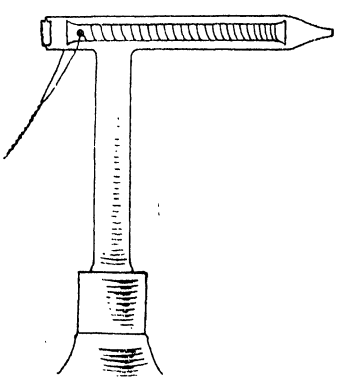
FIG. 6.

THE ELECTRO-THERMOGEN FOR GENERAL PURPOSES.

the patient on leaving that if it blistered it would do no harm but she should return and let me see it. This was at 10 A.M. At 2 P.M. she returned with the cleanest, most perfect blister I ever saw. It occupied the site of the neuralgic spot. It was of the size and shape of a half-walnut and filled with a serum of a deep orange colour. On again questioning her as to pain she said: "I felt no pain then from the heat nor do I feel any now from the blister." The neuralgia did not return.

Another patient, aged twenty years, had suffered for eleven months from severe pain affecting the left ear. The auricle was tumid and so painful that she had been unable for months to rest that side upon the pillow. Thermal anæsthesia was present, and the result of treatment by hot air was a crop of small blisters clustered round the meatus. This was after five applications, but before the blisters appeared the pain had gone and the patient was able to sleep on the affected side. There was deafness on that side. The first day she could only hear the ticking of my watch when it was applied to the ear. At the end of the fifth day she could hear it 3 in. away. This leads me to hope that in the treatment of some cases of deafness associated with morbid conditions of the fifth nerve the treatment by a hot-air current may be of service.

In paralysis of the portio dura (where, of course, there is no cerebral lesion) we find a condition which, on theoretical grounds at least, ought to be benefited by the hot-air treatment. The history and appearance of such cases are familiar to most of us. A person in health exposes one side of the face to a slight draught, say, in a railway carriage or elsewhere. This is followed by pain, stiffness, and ultimately paralysis of that side of the face. The unequal balance so occasioned between the opposing muscles gives rise to great distortion of the features, but sensation remains unimpaired as the seventh pair alone is involved. Recovery may take place in three weeks or it may be delayed for years. Within such wide possibilities it is difficult to estimate the proportion of improvement which may be due to any treatment, but the stimulus conveyed by the hot air seems to favour recovery, and it is always acceptable and comforting to the patient.



The unexpected sometimes happens. A medical friend of mine had suffered from toothache for three days, and he informs me that five minutes' application of the hot air current by means of the electro-thermogen cured him. This was before the commencement of the winter session. The toothache had not returned when I last saw him on June 13th. Such a result I could never have anticipated. Another medical friend informs me that he has found it of benefit to a patient affected with twitching of the facial muscles. This was also an unexpected relief.

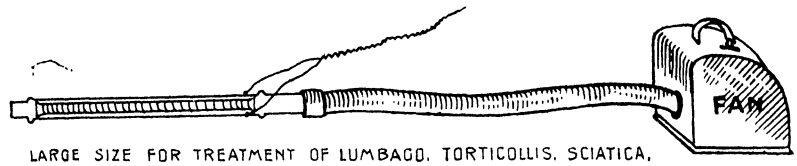
One evening a woman entered my consulting-room complaining that the act of swallowing caused her great pain on the right side of the neck. She informed me that she had suffered from a relaxed throat, which was better, but she appeared to be considerably run down. I asked her to swallow a mouthful of water and in doing so the muscles of the neck immediately jerked out in painful and continued spasm. I applied the hot air for ten minutes and she swallowed more easily, again for ten minutes and there was a further improvement, then again and at the end of half an hour she could swallow without wincing. The treatment was resumed on two following days for minor attacks, but no return of the spasm occurred after the third day. This was a purely functional disorder and it might have been relieved by other means; possibly a hypnotist might have been more speedily successful, and I merely give it as one variety of the cases in which hot air may be employed with some hope of success.

The electro-thermogen has also been of use in such cases as those in which medicated inhalations are usually of any avail. These include clergymen's sore-throat, spasmodic cough, asthma, bronchitis, and most other affections of the throat and larynx. In the initial stage of catarrh and in that distressing tickling cough which often accompanies or follows influenza I have found that a solution of cocaine in oil of cloves when volatilised and inhaled gives considerable and often speedy relief. In cases of sciatica accompanied by cough in which each paroxysm produces a sharp pain in the area of the affected nerve I have found that such an inhalation relieves the cough whilst the application of hot air to the pained limb relieves the sciatica. The chief advantage possessed by the hot air over steam seems to be that the substances administered are volatilised instead of vapourised, so that the particles are much more finely disintegrated and are conveyed to the air-passages by dry heat without the accompaniment of steam, which is less penetrating and always leaves a disagreeable and dangerous moisture about the face and neck.

By the kindness of Dr. Allan Jamieson I have been placed in possession of an unexpected addition to the list of ailments

FIG. 7.

FOR CAUTERIZATION



in which the electro-thermogen may be of possible service. He has drawn my attention to a paper in *La Presse Médicale* of Oct. 30th, 1897, in which M. Hollander of Berlin relates

Digitized by Google

how he treated a case of lupus of the face by a current of air heated to the temperature of 300°. For this purpose he employed a gas flame in which was placed a pointed metallic tube which became very hot. The air was blown through this by means of an indiarubber hand-bellows and so heated. The hot air current produced an escharotic effect on the diseased surface with great exactitude, without metallic contact and without encroaching as steam does on the healthy textures adjoining. The result, as shown by the illustrations accompanying the article, was very successful. In similar cases the electro-thermogen shown with the pointed nozzle may be found useful (Fig. 7) for cauterisation.

For the treatment of lumbago, torticollis and painful affections of the knee joint and other large surfaces I have used the larger apparatus shown in the illustration (Fig. 8). In this the air is blown from a separate fan in a much stronger current. The glass tube is from 14 to 18 in. long and 1¼ in. in diameter. It is adapted for the full voltage of the electric supply without the intervention of resistance lamps, and is very convenient and effective in the treatment of the diseases named as well as those cases of shingles which are accompanied and followed by persistent pain.

FIG. 8.

LARGE SIZE FOR TREATMENT OF LUMBAGO, TORTICOLLIS, SCIATICA, AND AFFECTIONS OF LARGER JOINTS.

Edinburgh.

A CASE OF FRACTURE OF THE INNER TABLE OF THE SKULL WITHOUT INJURY TO THE OUTER TABLE.

BY R. F. STANDAGE, L.R.C.P. LOND., M.R.C.S. ENG.,
CAPTAIN I.M.S., S.M.O. UNYORO FIELD FORCE.

DURING the fighting against the Soudanese mutineers around Jaruba Fort on the east bank of the Nile a picket of the enemy was surprised on Jaruba Hill, and a corporal, a Somali in the Uganda Rifles, received a Martini bullet wound on the left side of the head while pluckily rushing a hut held by the enemy. This occurred at 4 A.M. on Aug. 4th, 1898. He was dressed by the hospital assistant who described the wound as a "scalp wound." I saw the patient at 5 A.M. The man was pale, with a small, thready pulse, and said that he had been sick. He did not complain of pain in the head, but showed me his right hand in which there was a sensation of "pins and needles." He was extremely excited, rushed wildly up and down the small hill fort which he had assisted in taking, and was very anxious to join in the advance on the main fort which was just beginning. I was much hurried, as firing had commenced, but I thought it as well to examine the wound, though I was assured that the bone was not injured. My examination confirmed this and I ordered the man to be put on a stretcher and went off to join the general advance. The attack successfully concluded, this man, with other wounded, was carried back to the base hospital at Mruli and I accompanied him. He vomited twice on the road. On arrival at the hospital he was put to bed and a careful examination of his condition was made. This showed that the temperature was sub-normal and that the pulse was 90 and small; that the pupils were contracted and equal and responded naturally to light, and that the tongue was clean and protruded in the middle line. The patient answered questions perfectly rationally though somewhat slowly. He complained of thirst and of pain in the right hand, the grasp of which was weakened. It was supposed that he had fallen on the hand and that the weaker grasp was due to stiffening of the tendons. The scalp wound was in an oblique direction from right to left and from before backwards, was 3¼ in. long and situated over the upper part of the left parietal bone. The bullet had ploughed through the tissues of the scalp, making a long furrowed wound. In the middle of its course it had removed a small piece of pericranium, exposing the skull over an area as big as a threepenny-piece. A most careful examination with the fingers and a probe failed to disclose any depression or fracture of the outer table of the skull. I roughly mapped out the line of the Rolandic fissure by joining a point 2 in. behind the bregma to a point 2¾ in. behind and 1 in. above the right external angular process. The point of impact of the bullet on the skull was found to be ¼ in. behind the lower half of the upper third of that line. The wound was antiseptically dressed and a calomel purge was given and milk diet was ordered.

On the next day (August 5th) the patient's temperature was 99·2° F. During the night he had two attacks of bleeding from the nose. His tongue was clean and protruded straight. The pupils were normal and reacted to light and accommodation. The pulse was 96 and much fuller and somewhat hard. I had no apparatus for examining the urine. The condition of the right hand was much the same. The fingers could only be moved slightly, and though he could take hold of my hand he could not forcibly grasp it. His answers to questions were slow and not always to the point. This, I thought, might be attributable to his limited knowledge of Hindustani—our only common tongue—so I ordered his native officer to ask him questions in Somali. The officer reported him to be "very stupid." He complained of hunger, but was still kept on milk diet with some sago. On May 6th he had complete paralysis of the right hand and forearm and of the biceps muscle. He could extend his forearm when he was told to do so and hold the arm out, though with a distinct wrist drop, but in order to raise the hand to the mouth he had to employ the other hand. There was right facial paralysis with inability to purse up the lips or to whistle. The tongue was protruded to the right of the mid-line. The movements of the right leg were perfect and the knee-jerks were normal. The right pupil was slightly dilated, irregular, and immobile; the left was small and reacted to light. The temperature was 100° and the pulse was 90 He was conscious, but drowsy, and had to be awakened to answer questions, dosing off between each question and lying in his cot in a position of general flexion. Hæmorrhage between the dura mater and the bone was diagnosed and I decided to trephine at once at the site of the injury. The head was shaved and thoroughly washed with antiseptic solution and dressed till the hour for operation with lint soaked in perchloride of mercury solution (1 in 1000). All preparations having been made and the instruments boiled he was put under chloroform by my assistant, Mr. Salvee. An incision 4 in. long was made in the line of the bullet wound and another crossing it at right angles. The four triangular flaps were turned back and the pericranium with them. At the point of impact of the bullet there was a small dark discolouration caused by the scrape of the lead bullet against the bone, but no fissured fracture or depression was found. The pin of the trephine was inserted over the discoloured part and a disc of bone removed. A fissure of the inner table was found crossing the disc in an upward and backward direction and attached to the disc of bone was a firm clot of venous blood as big as a hazel nut. It was evidently caused by venous oozing from the diploë. This clot impinged on the dura mater and compressed it and the subjacent brain, but beyond this the dura, mater was healthy, it did not bulge in the trephine hole, and pulsated normally. A careful exploration with an

Digitized by Google

aseptic grooved needle did not find blood below the dura mater, so the wound was washed out with warm perchloride solution and closed with silkworm gut sutures, which at the base hospital were kept permanently in 1 in 20 carbolic acid solution. Though this clot was found and removed, and though there was a distinct improvement of intelligence and some return of power to the biceps muscle on August 7th, I was anxious about the patient as I could not reconcile the production of so marked a brachial and facial monoplegia with a clot compressing the motor area for the lower limb, which was absolutely unaffected. I was therefore prepared to trephine again lower down on the first indication of compression persisting over the brachial and facial area. On August 8th the patient was conscious, answering questions slowly but sensibly. The paralyses were the same. The right pupil was more dilated and was still immobile. The pulse was 90 and the temperature was 100·8°. At 2 P.M. he suddenly became unconscious with stertorous breathing and a hot, sweating skin, and at 2.30 P.M. he had a spasmodic seizure of the right side of the face, both eyelids, and the right arm and forearm. The forearm was flexed and the wrist was flexed on the forearm, the thumb was forcibly pressed into the palm, and the fingers were clenched on it. Both eyes were twisted to the right and both pupils were widely dilated and immobile. This spasm lasted till 3 P.M., when the twitchings gradually ceased, the face being the first to recover. At 3.30 P.M. I again applied the trephine, having reopened and enlarged the old wound downwards. It was united by first intention. Two discs of bone were removed, one over the middle third of Rolando's line and the other on the same plane but in front of the line. The intervening bone between these two discs and the old one was removed by Hey's saw and bone forceps. It was then found that an angular piece of the inner table had been fractured, the angle pointing downwards and being almost directly over the fissure of Rolando. The sides, formed by fissured fractures, extended upwards on either side of the line over the ascending parietal and ascending frontal convolutions. From these fissures venous oozing had occurred resulting in a circumscribed clot of the size of a walnut lying over the middle third of the Rolandic fissure and the adjacent convolutions. There was no hæmorrhage below or wound of the dura mater, or evidence that the fracture of the inner table was sufficiently depressed to compress the brain. The clot was removed and the wound was closed as before. The course of the case after this was uneventful. The patient did not recover consciousness. He had no further spasmodic attacks but he gradually sank into a deeper and deeper state of coma and died on August 13th. I was exceedingly anxious to obtain a post-mortem examination, but Somali superstition was deaf to the voice of science, his comrades objected and my case was left incomplete.

Stationed 800 miles from civilisation and nearly as many thousand miles from a medical library I cannot now refer to the literature of this subject, but I believe that fracture of the inner table of the skull with no discernible injury to the outer is of sufficiently rare occurrence to warrant the publication of this case. That the splintering of the inner table did not radiate from the point of impact of the bullet is peculiar, but is not inconsistent with the theory of diffusion of force widely over the table not directly struck. I certainly expected to find a star-shaped fracture immediately beneath the point struck by the bullet, and this expectation led me to trephine there and not over the brachial area in the first instance. I do not think that by so doing the result would have been altered, as it is probable that severe laceration of the brain substance, if not a fracture of the base extending across the anterior fossa, was present. The occurrence of epistaxis would suggest the latter. Certainly the tremendous energy of a Martini-Henry bullet, striking the skull at five yards from the muzzle, would be sufficient to produce either lesion.

Unyoro, East Africa.

BARRY SCHOOL BOARD.—The triennial election of the Barry School Board took place on Nov. 18th, when nine members were elected. Of their number three were members of the medical profession—viz.: Mr. Peter J. O'Donnell, L.R.C.S. Irel., Mr. John L. Livingston, M.D., C.M. Glasg., and Mr. William Lloyd Edwards, L.R.C.P. Lond., M.R.C.S. Eng. The first-named of these gentlemen was returned at the head of the poll.

CURE OF LEFT CAROTID ANEURYSM BY MANIPULATION.

BY RICHARD SLOCOCK, B.A. OXON., M.R.C.S. ENG., L.R.C.P. LOND.,

HOUSE SURGEON TO THE ROYAL PORTSMOUTH HOSPITAL.

A MAN, aged twenty-eight years, healthy, of spare build, was admitted into the Royal Portsmouth Hospital, under the care of Dr. Lloyd Owen, on Sept. 14th, 1897, with a well-marked aneurysm of the left common carotid artery. He stated that a swelling, which gave him no inconvenience beyond a little neuralgia, had existed six weeks before admission. There was no history of injury or of syphilis. The pupils were symmetrical and normal. The swelling was situated near the bifurcation of the common carotid artery and was of about the size of a pigeon's egg, with most definite expansile pulsation both seen and felt. This ceased on compressing the artery below. Its walls were so thin that an immediate operation was indicated. The patient, who was a nervous and apprehensive man, reluctantly consented to an operation. It was decided to ligature the artery below the sac. The patient, however, suddenly took alarm and obstinately refused to have any surgical treatment. It seemed dangerous for him to even move under his present condition. He left the hospital on Sept. 18th and sudden rupture of the aneurysm was feared. No more was heard of him until February, 1898, five months afterwards, when Mr. Bond, of Havant, to whom I am indebted for the following notes, wrote "that a few days after his return from the hospital he examined him, and to illustrate the nature of the operation necessary for cure he pressed firmly over the sac and artery. When next seen, two days afterwards, the beating in the neck had ceased and never returned. The tumour gradually diminished." And writing in April Mr. Bond reports: "There is not the least vestige of the aneurysm. It is completely cured. ..... He is quite well and in regular employ."

Illustration showing aneurysm of carotid.

This case may, I think, be regarded as a cure of carotid aneurysm, effected in an unintentional and unexpected manner by manipulation, a method introduced by Sir William Fergusson in 1862. Probably, when the aneurysm was being examined a detached clot became impacted in the mouth of the sac and acted as a check to the circulation. Such a happy termination to such a serious case must be rare, and is therefore of sufficient interest to be recorded as a welcome accident and not as a mode of treatment to be followed. No one would, except by accident, employ such treatment in aneurysm at the root of the neck, for the fear of producing head symptoms from embolism of the cerebral arteries must be very great. Two cases are reported[1] in which the examination for diagnostic purposes of carotid aneurysm produced paralysis and death. This case confirms the observation[2] that carotid aneurysm is more common in men than in women (of 88 cases of this disease 55 were those of men and 28 those of women, the sex in 5 not

being stated) and also that a very large proportion of cases of aneurysm of the carotids, 87·25 per cent., belongs to the common carotid at or near the bifurcation.

My thanks are due to Dr. Lloyd Owen for permission to publish the case and to my colleague, Mr. C. H. Newby, for the illustration.

Portsmouth.

INJECTION OF SALINE SOLUTION IN SHOCK.

BY W. THELWALL THOMAS, F.R.C.S. ENG.,

HONORARY ASSISTANT SURGEON TO THE LIVERPOOL ROYAL INFIRMARY; ASSISTANT LECTURER IN SURGERY, UNIVERSITY COLLEGE, LIVERPOOL.

WHEN an animal is killed by bleeding all the blood does not escape, yet the animal dies. The quantity remaining in the tissues, although containing a large number of blood cells, is of no use because it ceases to circulate, a small stream being unable to travel by reason of the great inequality between its size and that of the large vessels. The heart has little or nothing to contract upon, and even if a little blood gets into the large arteries the vessels cannot pass it along. The more sudden the loss—i.e., the larger the divided vessels—the quicker the collapse and death; slow loss of blood allows time for transudation of fluid into the vessels from the tissues and thus enables the circulation to be quietly, though often very feebly, carried on. In surgical cases where large vessels are divided serious collapse may be produced, or even death. In the serious cases the pulse becomes imperceptible at the wrist, the skin ghastly pale, the lips and mucous membranes almost white, and failure of respiration heralds death. In such an alarming sequence promptitude on the part of the surgeon may avert a fatality. What he has to do is to quickly stop the leak (if possible) and provide the necessary blood or liquid.

Transfusion of arterial or venous blood necessitated a hero or heroine willing to part with the requisite amount and a cumbersome, complicated apparatus. These conditions were not often found together and even when they were only occasional good results were recorded, for the mortality was very high. Experimental research demonstrated that coagulation emboli were the cause of death. Blood from the lower animals always produced disintegration of the corpuscles, so its use was quickly abandoned. In 1862 Nussbaum[1] suggested defibrinated blood to diminish the risk of emboli, but its preparation in an emergency being somewhat tedious and necessitating several processes soon placed it out of court. Goltz recognised the salient fact that death from loss of blood was really due to loss of liquid from the vascular system, and that any suitable solution—e.g., saline solution or artificial serum—would do for injection. This was an important advance. It is only within recent years that the practical application of the truth has been realised and the lectures delivered by Dr. Wm. Hunter in 1889 at the Royal College of Surgeons of England[2] had a large share in emphasising it. He showed (1) that the immediate source of danger from sudden loss of blood is the rapid fall in blood pressure; (2) that the value possessed by transfused blood is almost solely physical and dependent upon its volume; and, lastly, that all the advantages of transfused blood can be more readily and safely obtained by the use of simple saline solution. Normal saline solution, 6 parts of sodium chloride to 1000 parts of sterilised water, promptly injected into the venous system, will wash up the stranded corpuscles and give the heart something to contract upon—liquid within—its normal stimulus, and enable the circulation to be carried on and the oxygenation of the red blood cells to proceed. If the patient be not too old, manufacture of new blood cells goes on rapidly and in a few hours the change produced is little short of marvellous, and anyone for the first time seeing a patient saved even when apparently at his last gasp will be astonished at the effect.

The emergency method of dissolving a teaspoonful of common salt in a pint of hot water gives about 1 in 875, but for all practical purposes it is near enough. When patients are only suffering some degree of collapse short of imminent peril the solution may be injected into the rectum. In the same way hot saline solution left in the peritoneal cavity during abdominal operations produces rapid improvement in the patients. The fluid may be injected by pressure into the cellular tissue, under the mammary gland, in the groin or in the axilla, and by becoming absorbed takes the place of the lost liquor sanguinis, but all these methods are only serviceable when circulation is proceeding and absorption possible, and are of necessity slower in their action than injection into the veins direct. In extremis, nothing short of salt solution directly into a vein is of any use. For this purpose the apparatus generally used by me consists of a glass syringe (capacity 4 oz.), 2 ft. of rubber tubing, and a curved metal canula to fit a vein of the size of the median basilic vein. The wad of the piston is made of sterilised gauze; the material generally found on the piston when it leaves the maker's hands consists of white, clean looking material in the superficial layers, but "abominations" underneath in the shape of common—very common—tow, a whited sepulchre in truth. The piston is withdrawn and the whole apparatus filled with salt solution before fitting the canula into the vein, to prevent, of course, entrance of air into the venous system. The canula is tied into the vein selected and the syringe is elevated; if the fluid does not run in quickly enough the piston is inserted and the solution is forced in. A finger-and-thumb clamp of the tubing at the nozzle of the syringe enables the syringe to be withdrawn, filled again, and reapplied, and so on until enough fluid has been forced in. I have used a Higginson's syringe as the motive power. The following three cases illustrate the value of resort to saline injection.

CASE 1.—On Oct. 5th, 1894, a man was brought to the Liverpool Royal Infirmary on a police ambulance with his "throat cut." The out-patient clinique was being conducted at the time, so no delay occurred, although half-an-hour must have elapsed since the incision had been made. The man was unconscious, deathly white in colour, and pulseless, even in the exposed cut common carotid. The lower jaw spasmodically dropped with a feeble inspiratory effort. There was a deep gash in the left side of the neck. The internal jugular vein was cut clean through, the cut ends being three-quarters of an inch apart; the common carotid was cut into and the external and anterior jugular veins were divided. There was no blood escaping from the cut vessels; he had lost all the blood which it was possible to lose. The cut vessels were clamped; a small jerk of blood—less than a teaspoonful—escaped, however, when the common carotid was clamped. He seemed to be as near death as it was possible to get. I exposed the left median basilic vein by an incision to which the patient did not object—being no doubt "too far gone"—and 20 oz. of normal saline solution were slowly injected. After 7 oz. he took a short, distinct, inspiration; at 10 oz. a deeper one; the carotid was noticed to pulsate at 15 oz. and his breathing became regular and deep; and at 18 oz. he opened his eyes but did not appear to be conscious. His radial pulse was distinctly felt. The injection was stopped, all the clamped vessels were tied and a dressing was hurriedly applied. Thus far the treatment had been carried out on the ambulance, elevated at the foot. He was then wheeled to bed, surrounded by hot water bottles, and the foot of the bed was raised 18 in. An hour later he had sufficiently recovered to answer when called loudly to. He rapidly improved in condition. On Nov. 5th, owing to secondary hæmorrhage, he became collapsed. A quart of hot saline solution was injected into his rectum; all of it was absorbed and acted most beneficially in reviving him. This patient died two and a quarter years later and the unique dissected specimen of the neck is in the museum of University College, Liverpool.

CASE 2.—A man, aged twenty-five years, had to lose his leg and part of his thigh on account of extensive suppurative (gummatous) disease of the knee-joint. The operation was perforce performed through diseased tissues by Mr. Hamilton on Oct. 13th, 1896. The flaps were loosely brought together. The stump appeared to be healing well when, on Nov. 2nd, the twentieth day, at 8 P.M., he suffered from severe secondary hæmorrhage. The ward sister promptly applied a tourniquet, but he had lost a large quantity of blood. The house surgeon, Dr. Graham Martin, on being summoned, realised the extreme gravity of the case. In the absence of Mr. Banks and Mr. Hamilton I hurried to the Infirmary. The patient was very much emaciated

[1] Medical Times and Gazette, vol. i., 1862, p. 600.
[2] Quoted by Erichsen: Science and Art of Surgery, tenth edition, vol. i., p. 411.

Digitized by Google

by his previous disease and collapsed from loss of blood. He was taken to the operating theatre, where a few whiffs of ether were administered. The flaps were torn open, when the oozing of blood appeared to be coming from the femoral vessels—arteries and veins. A ligature was rapidly passed around the group by means of a Macewen's hernia needle and tied. An incision was then made over the common femoral artery, when a mass of suppurating glands was found; these were roughly thrown out by finger dissection, and the artery exposed, which was barely pulsating. His condition was so desperate that I clamped the artery and at once injected saline solution into the median basilic vein with a Higginson's syringe through rubber tubing and a canula. He quickly improved, and when a pint and a half had been injected the artery pulsated vigorously. It was now tied in two places and cut between. Suitable dressings were applied. Next morning he was out of all danger, and he recovered rapidly. He would surely have succumbed on the table had he not been filled with salt and water—of that we all felt certain.

CASE 3.—On Oct. 7th of this year a strong, muscular young man, twenty-six years of age, was brought to the Infirmary with his right leg and part of the thigh mangled, the result of an accident received during railway shunting operations, a wagon having passed over his leg. The ambulance on which he had been carried bore evidence of the inefficiency of the three tourinquets which had been applied, there being at least a pint of blood on it. He was ghastly pale and his radial pulse was scarcely perceptible. A few whiffs of ether were administered and an amputation through the middle of the thigh was performed and the main vessels were tied. When the tourinquet was liberated the pulsation in the femoral vessels was so feeble and his general condition so critical that I injected saline solution into the internal saphena vein in the flap. I went on pumping until the main artery pulsated vigorously in the stump and the colour returned to his face. The flaps were rapidly sutured and a glass drainage-tube was inserted behind. That night his temperature rose to 100° F.; next morning it was normal, and he looked so well that no one seeing him would ever have guessed that he had suffered from amputation through the thigh so recently. On the second day he felt so well that he wanted to know "why he was not allowed meat and potatoes like the man in the next bed." His pulse was markedly dicrotic. The stump healed by first intention and on the twentieth day he was up and about the ward.

The ward sisters have noticed that patients perfused always appeared to have a good night after the operation and rarely complained of pain. The solution appeared to possess anodyne properties.

In other cases where local and general conditions were not so favourable temporary resuscitation took place. In one of these a thin, anæmic woman with a septic, discharging pyonephrosis, during an operation for extirpation of the kidney, collapsed on the table. The condition could hardly have been from loss of blood, for the kidney pedicle was securely clamped. I injected a little over a pint of saline solution into the median basilic vein with immediate effect in both restoring respiration and circulation. She, however, died on the third day. In another case—one of extensively-fractured skull—the man appeared to be dying on the table during an operation for tying both branches of the middle meningeal artery by Mr. Rushton Parker. Injection of 15 oz. of salt solution brought him around, but, alas, only to start fresh bleeding from a long rent in the superior longitudinal sinus—beyond repair. He succumbed. From observations extending over some years I am convinced that in saline flushing of the abdomen, injection into the rectum or into veins, we have a most valuable, probably the most valuable, means of dealing with collapse, whether due to loss of blood or not.

In cases which are not extreme, elevation of the foot of the patient's bed 12 in. or 18 in. and the injection of a quart or more of hot saline solution into the rectum by means of a Higginson's syringe, with a French catheter on the nozzle so that the fluid can readily enter the colon, acts in a few seconds like a charm; the fluid disappears like water on a blotting pad. It is of very little use in such patients to endeavour to stimulate the heart by ether or alcohol; what it needs most is a physiological stimulus from within its walls. I have resorted to this proceeding so often and with such gratifying results as to consider it my stock treatment for collapse.

I have not thought it necessary to give weary details of every case, my object in drawing attention to saline injections is merely to emphasise the simple and powerful means at our disposal. While conscious that much has been written on the subject, still I think saline injection is not sufficiently often resorted to by surgeons.

Liverpool.

A CASE OF EMPHYSEMA, A SEQUEL OF MALIGNANT DISEASE OF THE SIGMOID FLEXURE.

BY H. KERR, M.A., M.B. GLASG.,
ASSISTANT MEDICAL OFFICER, BUCKS COUNTY ASYLUM, STONE, AYLESBURY.

EMPHYSEMA arising from a communication with the alimentary tract must, I think, be somewhat rare, and on that account I venture to put on record the following case, the patient in which was an insane inmate in the Bucks County Asylum.

The patient, a female, had been resident in the asylum for thirty-six years and at the time of her death she was sixty-six years of age. She was quite demented and unable to give any account of her symptoms. She enjoyed good bodily health and was well nourished, and until the onset of acute symptoms she showed no signs of disease. The first thing which called attention to her condition was that during the night she vomited and appeared to have pain in the epigastrium. On examination in the morning she looked pale and ill. The pulse was 96 per minute, weak, and thready; respiration was shallow and increased in frequency; and her temperature was 98·2° F. Extensive emphysema, indicated by characteristic crepitation, was found present over the whole of the left side and back, extending from the axilla and front of the chest to the left iliac region in the front of the abdomen. No fracture of ribs, which suggested itself as the most probable cause, could be ascertained, and there was no history of any violence. Some swelling was noticed in the right iliac region over the sigmoid flexure; this disappeared on manipulation and was considered to be due to gas in the large intestine. In the evening the patient's temperature was 100°. On the second day the emphysema was more extended and the swelling over the sigmoid flexure was more pronounced, although it could still be in great part reduced, returning almost at once. The bowels had not acted and an enema was given, the fluid being rejected forthwith. However, after the injection of 4 oz. of olive oil she had a loose motion on that day and on the following days fæces were passed in small quantity. Her pulse was 120 and her temperature 101°; the skin over the lower part of the chest and back was red and indurated, that over the swelling in the iliac region being natural. During the next four days her condition became gradually worse; the temperature ranged from 101° to 102°, the pulse varied between 120 and 140 and was very weak and thready, and the respiration was increased. She also vomited on one or two occasions, the vomited matter being dark in colour and slightly fæculent in odour. She died on the seventh day from the onset of acute symptoms. The treatment was simply directed to combat the tendency to collapse, and she was put on milk diet and given stimulants.

A post-mortem examination was made on the day after death. On opening the chest air was found present in the tissues of the chest wall, and at the lower and back parts of the chest there was diffuse suppuration which was more marked in passing downwards. In the left iliac region a cavity of some size was found, the contents being liquid fæcal matter and gas; and on the floor of this cavity a small opening was found to communicate with the intestine, admitting an ordinary probe easily. On opening the abdomen the sigmoid flexure was found firmly adherent to the abdominal wall over an area rather larger than a crown-piece, and the intestine at this point was found to be the seat of a new growth, firm in character, involving the whole circumference of the bowel, and causing such narrowing of its lumen that it would only admit the forefinger with difficulty. The surface of the tumour was ulcerated, and at the point of adhesion to the abdominal wall was a small opening leading to the cavity on the surface. The intestine above the flexure was much

Digitized by Google

dilated and contained a quantity of liquid fæces. The small intestine was also somewhat dilated, and the contents of the stomach were dark in appearance and slightly fæculent in smell. The other organs presented nothing noteworthy, except the heart, which was very fatty. The tumour on microscopical examination was found to be of the nature of a columnar-celled epithelioma.

The points of interest in the case appear to be the probably long duration of malignant disease with stricture of the bowel giving no urgent symptoms; the supervention of extensive emphysema from a communication between the tissues of the abdominal wall and the bowel; and the difficulty in forming a diagnosis of the condition and of being sure that it was not due to fractured ribs, certainty being only assured by the post-mortem examination. The immediate cause of the condition was probably the increased pressure of the intestinal contents arising from the stricture acting upon a part of the diseased bowel weakened by the process of ulceration.

Stone, Aylesbury.

TETANY AND TETANOID SPASMS ASSOCIATED WITH GASTRIC DILATATION TREATED SURGICALLY.[1]

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,

SENIOR SURGEON TO THE GENERAL INFIRMARY AT LEEDS; PROFESSOR OF SURGERY IN THE YORKSHIRE COLLEGE OF THE VICTORIA UNIVERSITY.

AN interesting paper by my colleague, Dr. Trevelyan, in THE LANCET of Sept. 24th, 1898, has attracted my attention to the importance of a symptom—tetany—which in the severe form described in his paper is manifestly a rare disease, but of which Case 1 in the present paper is a good example. It does not seem, however, to have been generally noticed that severe muscular spasms of a tetanoid character, possibly allied to if not really an early stage of true tetany, are frequently associated with gastric dilatation; yet it is a symptom which in a more or less severe degree frequently attends pyloric obstruction and which I have come to look on as a very frequent concomitant of the disease. A careful study of Dr. Trevelyan's paper leads one to the conclusion that fully-developed tetany, in association with stomach dilatation, is a symptom of extreme gravity and that in such cases a fatal termination is to be feared in a considerable percentage of cases. To quote from Dr. Trevelyan's paper: "If the term 'gastric tetany' is allowed to include the milder as well as the severer cases, and there is no sufficient reason against this view, then the disease may turn out to be more common than is usually supposed. The transition between gastric tetany strictly so-called, tetany with gastro-intestinal symptoms, and ordinary tetany would seem to be a gradual one. The prognosis of tetany occurring in gastric dilatation is undoubtedly very serious; nearly 75 per cent. of the cases die. The largest mortality occurs in the groups 2 and 3 [referred to in Dr. Trevelyan's paper], that is, where the spasm in the extremities is associated with tonic spasm in the head and trunk muscles or with clonic spasm. If the very strict views are held as to the disease then the outlook is almost hopeless; thus of the 11 cases recognised by Frankl Hochwart only 1 recovered. There is a danger here, as in some other diseases, that the fatal issue is raised to be the chief criterion as to the nature of the affection."

My own experience of tetany and of the severe muscular spasms in association with gastric dilatation leads me to think that we may possibly take a more hopeful view if the cases be treated surgically at an early period. I hope on some future occasion to report my experience in dilatation of the stomach treated surgically, as it has fallen to my lot out of nearly 60 operations which I have performed on the stomach to operate for this condition in nearly 30 patients, several of whom have had tetany or severe muscular spasms in a more or less pronounced degree. The following cases will serve to illustrate my remarks. In the first, the tetany was so pronounced that the question of strychnine poisoning crossed my mind. In the second and third cases, though there were well-marked tetanoid spasms, the cramps were limited to the extremities and the abdomen.

[1] A paper read before the Leeds and West Riding Medico-Chirurgical Society on Nov. 4th, 1898.

CASE 1.—A man was sent to me by his medical attendant in January, 1895, with a view to having something done in the Leeds Infirmary to relieve his condition. He had been suffering for five years from pain after the ingestion of food, with attacks of vomiting. Latterly his condition had become aggravated, the pains occurring from half an hour to one hour after each meal, being relieved only by vomiting, so that for the last six months he had had to give up his work as a printer. For some time before coming under my notice there had been very evident peristalsis from left to right in the epigastric region. Throughout the period over which his stomach symptoms extended his bowels had for the most part been very constipated, but there were occasional attacks of diarrhœa. During this time he had attacks of what he described as "cramps" in his limbs and especially in the legs. He had lost very considerably in weight, for in December, 1892 he weighed 9 st. 6 lb., whereas in January, 1895 his weight was only 7 st. 7½ lb. On examination there was found well-marked dilatation of the stomach, but the feature of the case which presents most interest in connexion with the present paper was the occurrence while under observation of severe tetanic spasms affecting almost all the muscles of the body. So extreme were these and so widespread (the muscles of the trunk and of the cervical region as well as those of the limbs being affected) that on Jan. 17th the question of possible poisoning from strychnine was raised. As palliative treatment of the stomach condition gave no relief he was submitted to pyloroplasty on Jan. 24th. The abdomen was opened and the diagnosis of cicatricial stenosis with hypertrophy of the pylorus was confirmed. The modified operation which I described some time ago[2] was done, a bone bobbin being employed. Recovery was uninterrupted, and although the cramps were present up to the time of operation he never had even a threatening of cramp afterwards. On Feb. 15th he was able to take a mutton chop for dinner without inconvenience, and by March 2nd (five weeks after operation) he had gained 8½ lb. Since then he has done very well. Two years after operation he had quite recovered his strength and was working as usual, his weight then being just over what it was in December, 1892, and quite 2 st. above his weight at the time of operation. There has been no recurrence of any "cramps" or of muscular spasms of any kind. In a letter received at the beginning of last month he speaks of some slight symptoms which may have had their origin in some stomach disorder, but he adds, "you will please understand that I am a new man to what I was when you saw me last."

CASE 2.—A man, aged twenty-four years, was seen by me on Oct. 5th, 1897, in consultation with his private medical attendant, on account of severe painful cramps of the extremities and of the abdomen with persistent vomiting. He gave the history of having had pain after food several years previously and of having vomited blood, since which time he had never been well and had gradually lost flesh. For some little time before I saw him he had vomited every day unless the stomach was washed out, and his weight from being over 10 st. had diminished to a little over 8 st. There was well-marked dilatation of the stomach but no pyloric tumour could be felt and simple stricture of the pylorus was diagnosed. He was admitted to the infirmary in October, 1897, and on the 21st of that month I performed pyloroplasty, as the pyloric orifice would only permit the passage of a No. 10 catheter. The transverse incision in the pylorus was sutured vertically over one of my bone bobbins. Recovery was uninterrupted, and from that time the cramps and vomiting ceased. He returned home within the month. On Oct. 23rd of this year I received from him the following letter: "It is with a grateful heart I write to thank you for the good received at your hands twelve months ago. I am thankful to say I have never had any trouble with my stomach since. I feel it my duty to acknowledge the good I received and also to thank you for your extreme kindness."

CASE 3.—A woman, aged twenty-nine years, was sent to me from the east coast in the spring of 1895, suffering from severe pain in the abdomen, associated with vomiting and loss of flesh; there was well-marked dilatation of the stomach, and the pain always started on the left of the abdomen and passed to the right, on which side, just below the ninth rib, there was well-marked tenderness with rigidity of the right rectus muscle. Operation was declined and I did not see the patient until

[2] Brit. Med. Jour., July 20th, 1895.

Digitized by Google

nearly the end of the year, when she told me that the pain in the abdomen was excruciating and that it recurred every day; she said it was associated with severe cramp in the limbs, especially in the legs and thighs, and that at night she was kept awake by the pain. Vomiting of large quantities of fluid occurred daily and she was steadily losing weight and strength. Her symptoms begun in 1888 and she had lost 2 st. in weight between that year and 1895. On Dec. 14th, 1895, I opened the abdomen and found the pylorus adherent to the gall-bladder, liver, and abdominal walls, and it was so much thickened as to form a distinct tumour. Pyloroplasty was performed after the adhesions had been separated. Recovery was uneventful and satisfactory in every way and she returned home within the month. She never had any return of the tetanic symptoms, and a report sent to me in March was to the effect that she had gained flesh and was well. The further history of the patient is not germane to the present paper. It will therefore suffice to say that in July, 1896, I saw her again, when she complained of stomach symptoms, but there was not much loss of flesh. Later the vomiting, loss of flesh, and well-marked stomach splash showed that the pyloric trouble had recurred. I performed gastro-enterostomy a month ago as I found a distinct tumour of the pylorus, which I believed to be simple inflammatory induration and not malignant, otherwise I should have excised the pylorus. The patient has made a good recovery and has returned home. The interesting point in her case is that there has never been any return of the painful cramps in the limbs since the first operation.

Though tetany occurs apart from gastric dilatation—for instance in children during teething, when it is frequently associated with gastro-intestinal disorders and not infrequently merges into general convulsions, and in other conditions apart from stomach disorders—yet tetany or painful muscular spasms of a serious character are so frequently associated with that condition that one cannot ignore the association as being merely accidental. It is curious that I have never seen the symptom in other than dilatation due to simple causes, such as adhesions to the pylorus, gall-bladder or liver, or in stricture of the pylorus due to the cicatrisation of ulcers. I have never seen it in simple unobstructive dilatation or in dilatation due to cancer of the pylorus, though Dr. Trevelyan gives single examples of its association with both in his paper.

The immediate cause of tetany is perhaps beyond the scope of a surgical paper, but as my views are based on clinical experience they may be worth relating. I have noticed that the exacerbations of the tetanic state, especially in the first case related, were always associated with a painful contraction of the stomach, and that when the wave of contraction had reached the pylorus, which was previously incapable of being felt, it formed a distinct hard tumour. The abdominal pain then became very intense and the tetanic cramps in other muscles came on, or if already present became intensified. From this sequence of events I have come to the conclusion that the cause of the tetany is a double one—(1) the absorption of some poison from the dilated stomach which increases the excitability of the nervous system and (2) a reflex effect produced by the painful contraction of the pylorus. The practical outcome of my paper is that where tetany is, or its allied conditions are, associated with gastric dilatation surgical treatment is well worth considering before the symptoms become so severe as to lead to the almost hopeless condition described in the report of some of the fatal cases.

Leeds.

THE USE OF MORPHIA IN CARDIAC DISEASE.[1]

BY F. S. TOOGOOD, M.D. LOND.,
MEDICAL SUPERINTENDENT OF THE LEWISHAM INFIRMARY.

BEFORE studying the clinical effect of morphia in diseases of the heart let us first consider what effect it has upon the heart and circulation in health. When a full dose of morphia is injected the first thing noted is some increase in the pulse-rate; this is effected partly through the cardiac centre and partly through the ganglia in the heart-substance. Then succeeds a period when the heart-beats diminish in frequency due to the stimulation of the vagus. If a sufficiently large dose be given this stimulation is succeeded by a period of depression or paralysis of the vagus which is shown by an increased frequency of the pulse due to the loss of balance between the inhibitory action of the vagus and the accelerator fibres. In the majority of cases, however, the intrinsic ganglia of the heart have ere this become paralysed themselves, so that they are unable to take advantage of the withdrawal of the inhibitory influence of the vagus, and so there is a persistence of the slow pulse, which gradually gets weaker and weaker until death ensues.

The action upon the vessels appears to be depressing from the first. The one period which physiologically suggests that morphia might be beneficially used in the treatment of cardiac disease is in the stage where the vagus is stimulated and the heart-beats are diminished in frequency. In the first instance I approached the subject entirely from the clinical side, and it was not until the treatment which had been begun in despair had proved of great benefit in several cases that I sought a physiological basis for that which is, I think, a clinical fact. Those books to which I have access universally agree in condemning the routine administration of morphia in cardiac disease, although most of them record the bald fact that it is occasionally useful. I have little to offer beyond the bare recital of the cases treated, but before considering these let me briefly glance at the action of the drug upon the kidneys, as it was here that I apprehended the greatest danger.

Of all the lessons which were hammered into me during my hospital career none was more persistently driven home than the fact that it is extremely dangerous to administer morphia in kidney disease or derangement; and as in an imperfectly working heart there is nearly always associated renal trouble, either in the shape of diminution in the amount of urine excreted or in the presence of albumin and diminution of the amount of urea and other excretives, so it may be imagined that I watched the quantity and quality of the urine passed by the patients under observation with much interest. Morphia can be detected in most of the secretions; a large proportion is excreted in the bile. It can also be found without much difficulty in the urine. The action of morphia is to diminish the amount of urine passed, to render probable the re-absorption of the drug from the dulled sensibility of the bladder, while in those cases where there is diminished excretory power of the kidney due to disease the danger of retention and accumulation of the drug on the system is sufficiently alarming.

I was first led to try the administration of the drug in those distressing cases of heart-disease (mainly of mitral incompetence) where the exhibition of digitalis and its allies, strophanthus and convallaria, appears to do nothing more than excite persistent vomiting and where the stomach retains practically nothing, where the heart is extremely irritable and irregular in rhythm and the pulse in volume, where often an ever-present dyspnœa renders the condition of the patient intolerable from exhaustion and from want of sleep, and where there may also be œdema from a failing circulation, and a scanty amount of albuminous urine. In these cases I have seen the hypodermic injection of morphia effect the most gratifying results. The pulse has become steady, strong, and regular, the œdema has disappeared, the dyspnœa has been relieved, and the urine, instead of being scanty, high-coloured, of high specific gravity, and containing albumin, has become normal in amount and character and the albumin has become much less or has entirely disappeared.

CASE 1.—A man, aged fifty years, was seen by me in consultation in June, 1897; he had been confined to his bed for two months and had been unable to go to business for six months. He was suffering from urgent dyspnœa which had prevented his sleeping for many days. His legs were œdematous and his urine was scanty, loaded with urates, and it contained one-tenth albumin. His pulse was small, easily compressible, 120 to the minute, and irregular in time and volume. His heart was enlarged, the apex beat occurring in the sixth interspace 1 in. outside the nipple line. There was a distinct systolic murmur heard best over the aortic area. Every drug which had ever been suggested as of use in cardiac cases had been tried and had proved of no avail. I suggested hypodermic injections of ¼ gr. of tartrate of morphia and the effect was marked from the first. He slept quietly and comfortably, the heart gradually came down to 80 beats in the minute, the urine increased to 70 oz., the albumin cleared up, and the œdema disappeared. The

Digitized by Google

dyspnœa varied a good deal and was from the patient's point of view the most troublesome symptom, but he was now free from it except slight paroxysmal attacks when the effect of an injection was wearing off. He gradually improved in general health and two months after the commencement of the treatment was able to take short walks in the neighbourhood and to resume most of his former occupations.

CASE 2.—This patient was a man, aged thirty-two years, a labourer, formerly a soldier, who was admitted to the Lewisham Infirmary from the casual ward on Oct. 5th, 1896, complaining of dyspnœa and pain in the heart. On examination he was found to have his apex beat in the nipple line in the fifth interspace, and to have a reduplication of the first sound and a diastolic murmur well heard at the base and conducted down the sternum. The pulse-beat was of the typical water-hammer character. The urine was of specific gravity 1020, acid and clear, and contained no albumin and no sugar. There was a history of rheumatic fever seven years ago. Under rest and digitalis he recovered his usual state of health, but on Oct. 21st of the following year he had a severe attack of anginal pain and dyspnœa which, unlike some of his previous attacks, did not yield to liquor glonoini or to amyl nitrite. It, however, was relieved by a mixture of 10 minims of liquor morphiæ and 1½ minims of liquor atropiæ sulphatis every four hours. These anginal attacks now began to recur more frequently but were not very severe and were always relieved speedily by the morphia mixture and in the intervals he was able to get about and to assist in the duties of the ward. On Nov. 1st I find a note that the liver and spleen could be distinctly felt below the ribs. From this time he took to his bed and became progressively weaker and thinner. On Dec. 8th a severe anginal attack necessitated the injection of ¼ gr. of morphia which at once relieved him. Although he took a fair amount of nourishment his emaciation became extreme; an occasional injection when he had any return of the pain kept him absolutely comfortable and he died from sheer asthenia on Dec. 12th, 1897. In this case I claim that morphia succeeded in relieving the anginal attacks when everything else had failed; that it had no bad effect but on the contrary always left him better than it found him; that it rendered his last weeks comfortable and gave him an easy and painless departure instead of an agonising end, without in any way shortening his days.

CASE 3.—A man, aged fifty-one years, a labourer, was admitted to the Lewisham Infirmary on Jan. 6th, 1897, complaining of pain in the chest in the cardiac area off and on for nine months and of dyspnœa for over a year. On examination his apex beat was found to be 2½ in. below the nipple and just outside the nipple line; there was also a loud aortic systolic and diastolic murmur. Under rest, stimulants, and cardiac tonics, including digitalis and strychnine, he gradually grew worse; he could not sleep and he vomited incessantly, and his condition was considered absolutely hopeless. On Feb. 3rd 15 minims of liquor morphiæ were added to his mixture and from that time he steadily improved; the morphia required to be increased once or twice and an occasional hypodermic injection of the same drug was used in anginal attacks, but he steadily improved, contracted a fresh lease of life, and took his discharge on June 5th, 1897, with his heart thoroughly compensated and doing its work well.

CASE 4.—A woman, aged thirty-four years, was admitted to the Lewisham Infirmary on July 28th, 1897, complaining of shortness of breath and of great weakness. There was a history of rheumatic fever twenty-four years ago. She was suffering from urgent dyspnœa, constant distressing cough, and had œdema of both legs. The apex beat was in the seventh interspace just outside the nipple line. The pulse was very irregular in force and frequency, over 120, and could scarcely be counted. There were well-marked systolic and presystolic murmurs. There were râles and rhonchi all over the chest. The urine was of specific gravity 1024, acid, very dark, and scanty, was one-third albumin, and contained no blood and no sugar. Rest, digitalis, and stimulants did not afford any relief and on August 3rd persistent vomiting set in which the omission of the digitalis did not relieve. On August 12th 10 minims of liquor morphiæ were given every four hours. The effect was marked from the first; the vomiting ceased and the urine became more copious, increasing steadily from 10 oz. to from 60 oz. to 70 oz. in the twenty-four hours. The albumin gradually decreased, and on Sept. 11th it disappeared altogether. It was thought that this might have nothing to do with the morphia, so on several occasions the morphia was withheld, but this was invariably followed by a marked diminution in the quantity of urine and by an increase in the amount of albumin. I will not weary you by a recapitulation of a convalescence. A too early withholding of the morphia caused a relapse which at once cleared up on the renewal of the dose and after a prolonged and careful probationary course of exercise she took her discharge on March 19th with no symptoms and with her heart presumably compensated for a time but still acting irregularly and with the murmurs quite as distinct as before.

CASE 5.—A woman, aged twenty-four years, was admitted to the Lewisham Infirmary on Dec. 2nd, 1897, complaining of "pains in the heart." She was thin, anæmic, and slightly yellow. The apex beat was in the fifth interspace and gave no evidence of hypertrophy or dilatation. The action of the heart was irregular and quick and the pulse was easily compressible. There was a loud mitral systolic murmur heard. The first sound was suggestive of mitral obstruction. Rest and iron were prescribed. On the 22nd, there being no improvement, 5 minims of tincture of digitalis were ordered. A slight improvement followed, but on Feb. 10th her condition, which had been very carefully watched, became very alarming. The action of the heart became tumultuous, there was great cardiac pain, and a distinct presystolic murmur developed. 4 oz. of stimulant in the twenty-four hours were ordered. On the 12th the pulse was almost imperceptible and the patient was in a state of collapse and apparently dying. She was only passing 16 oz. of urine in the twenty-four hours and was vomiting incessantly. The digitalis was omitted. A hypodermic injection of ¼ gr. of morphia was given every twelve hours and the patient did what she had not done for many days—viz., she slept soundly. She immediately began to improve; the vomiting ceased, the urine became normal in amount, and the tumultuous action of the heart subsided. The presystolic murmur became less and less pronounced and the action of the heart more and more regular, until by March 17th the presystolic murmur had entirely disappeared and the heart's action was absolutely regular, although a well-marked mitral systolic murmur remained, and the patient was to all intents and purposes well.

I have chosen these 5 cases as being fairly good examples of the beneficial results of this method of treatment, although many more might be cited, and I may say here that I have had no accident. That morphia in large doses is a cardio-vascular depressant is well known, but its sedative and soothing effects upon irritable conditions of other organs are so well recognised that I am inclined to think that the undoubtedly beneficial results in cardiac disease are due to its action upon the nervous apparatus of the cardio-vascular system, both central and local, bringing rest to an overstrained organ and allowing it the chance of developing its recuperative power.

Lewisham, S.E.

A CASE OF

DEATH FROM DIABETES MELLITUS IN WHICH THAT DISEASE GAVE NO PREMONITORY SYMPTOMS.

BY T. WILSON PARRY, M.A., M.B. CANTAB.

A MESSAGE was brought to me at 8 o'clock on the morning of Nov. 9th that a woman living in a village some five miles from here had suddenly fallen down while in the act of dressing at 6 A.M. and could not "get her breath"; would I come at once? I started with the least possible delay and arriving at the house found that the patient, a woman sixty-eight years of age, had suddenly fallen, as my messenger had informed me, while dressing, without any previous warning of any kind and had been in a comatose state ever since. On examination I found the pupils to be contracted and only very slightly, if at all, reacting to light; the reflex was entirely abolished. All the limbs were flaccid and the knee-jerks were absent. I immediately put my stethoscope to the heart expecting to find an accentuated second sound (superficially diagnosing the case—from the suddenness of its onset, the age of the patient, and her previous apparently

Digitized by Google

good health—as an apoplectic seizure), but the heart sounds were normal in every respect. I was unable then to get a sample of her urine, as she had passed both urine and fæces under her and I had no catheter with me. As I had a couple of patients in that district to visit I returned to her in the course of about two hours and found her in precisely the same state as before. I could not make up my mind at all about its being an apoplectic attack and I was naturally anxious to examine the urine before giving the patient's friends a decided prognosis, and I fully explained to them the necessity of my so doing. Towards evening I called again and found her in the same completely comatose condition. I then drew off her urine. She died on the following morning at eight o'clock, her condition apparently having remained unchanged. The analysis of the urine gave the following results. It was acid in reaction; the specific gravity was 1023; a slight trace of albumin only was found, but a large quantity of grape-sugar was present, a few drops of urine only being necessary to reduce a large quantity of Fehling's standard solution. The amount of glucose present was 1·6 grammes per cent.

The points of interest in this case centre themselves as follows. The woman was, to all accounts, perfectly well up to the time she was seized with the coma; in fact, on Nov. 7th—that is, only two days before the attack came on—some one who was capable of judging had remarked how extremely well she looked and had told her this. She had not consulted a medical man for at least fourteen years. There was no history of anything which was not compatible with perfect health. There were not even any distinctive premonitory symptoms of diabetes mellitus, the disease she was undoubtedly suffering from. There was no emaciation—the general agreement was that she was getting stouter if anything; no undue thirst or hunger—she was very abstemious; no asthenia—she was strong and robust and worked hard; no polyuria—the woman who slept with her told me that she never got out of bed more than once in a night, if at all, to pass urine and that she had never complained to her of suffering either from extreme thirst or of passing more urine than she normally should. I have not the slightest doubt in my own mind that the coma in which this patient passed away was diabetic. The news brought to me, and which had evidently indelibly impressed itself on the mind of the messenger, that the woman could not "get her breath," bespoke the characteristic "air-hunger" which accompanies this coma, and the presence of a large quantity of glucose in the urine confirmed the diagnosis, in my mind, to an absolute certainty.

There is room for the suggestion that the coma was apoplectic and that the somewhat low specific gravity of the urine and the presence in it of some albumin, even although it was merely a trace, showed it to be renal in origin; but the condition of the heart, with its normal size, regular beat and rhythm, and sounds free from any murmur or accentuation—pulse without tension and arteries without atheroma—abolished from my mind entirely the apoplectic nature of the coma. Syphilis is practically unknown in this neighbourhood, and even if it were prevalent there were certainly no signs whatever to suggest that the patient was suffering from its tertiary effects. Epilepsy, too, has to be entirely abolished from the diagnosis as the coma was instant and was not preceded by any clonic or tonic spasms, nor was there any frothing from the mouth.

Summing up, then, this somewhat dramatic termination to an apparently absolutely healthy life—the suddenness of the onset of the attack suggestive of "stroke" but due in reality to hidden processes which must have been working in the dark for some definite appreciable time, the secret action of the disease culminating in a sudden attack and a short fatal illness of twenty-six hours—is to me a thing instructive in the highest possible degree. In the rush of general practice, when sometimes speedy examinations have to be made on account of quantity of work or lack of time, the practitioner is often tempted to neglect to examine the urine for sugar unless the patient exhibits symptoms suggestive of diabetes. Such a case as the present one has vividly brought to my mind the absolute essentiality there is of examining all urines for sugar, as well as for albumin, as there is the possibility that a person of apparently sound physical health may be suffering from a disease which may make itself manifest in an alarming way at any time but from the knowledge of which the patient himself may be happily entirely ignorant. It sometimes may be discreet to keep certain facts from a patient, but we should fail in doing our duty if we did not inform the relatives or friends of the patient of the possibly serious nature of an unsuspected disease. The legal aspect of such a case as this will at once present itself to the mind, hence again the vital importance of making it a habit to always examine the urine for sugar in every case taken in hand—an importance which to my mind cannot be overrated.

A CASE OF CEREBRAL TUMOUR:

RAPID ONSET OF CHARACTERISTIC SYMPTOMS; OPERATION; DEATH; REMARKS.

BY EDWARD ARMITAGE, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H. CANTAB.,

GOVERNMENT PHYSICIAN FOR THE WAILUKU DISTRICT; PHYSICIAN TO THE MALULAUI HOSPITAL, ISLAND OF MAUI, HAWAIIAN ISLANDS.

THE following case, bearing as it does upon the difficult question of the localisation of intra-cranial lesions, seems to me to be of interest, particularly so at a time when this subject is receiving so much attention and in view of the admirable address by Professor Augusto Murri of the University of Bologna, published in THE LANCET of Jan. 30th, 1897.

A male Hawaiian, aged about fifty years and residing in Wailuku, was admitted to the Malulaui Hospital on March 14th, 1895. He was brought to the hospital in a *nack* by his friends and was in an unconscious state on admission. Immediately after being carried into the male ward he was seized with an epileptiform convulsion. Being present at the time of his arrival I directed him to be laid on the floor of the ward until the convulsion had ceased, when he was placed on a bed and I at once proceeded to relieve the urgent symptoms. The patient was quite unconscious. His pupils were slightly dilated and, suspecting cerebral apoplexy, I bled from the left arm and applied a blister to the nape of his neck. This treatment was succeeded in a few minutes by the most encouraging results; he recovered consciousness, was able to speak and to recognise his relatives, as also an old friend who was a patient in the same ward. On inquiry from his relatives I learned that on the previous New Year's day he had fallen from the roof of his house; since which time he had suffered from headache until two days prior to his admission, when he had been seized with convulsions, unconsciousness, and vomiting of blood. Later I learned that he was in this state at least four days prior to admission, and I have no doubt that a "kahuna" or native soothsayer, had been consulted. On interrogating the patient, he told me that the headache affected the whole vertex but was particularly severe over the forehead. The patient was a strong-looking, well-developed man, profusely tattooed. On the right frontal region at the upper margin of the forehead and above the centre of the orbit was an old scar the posterior portion of which presented a fungoid granulation. His pulse was strong, regular, normal, and of high tension, and his temperature was 102° F. in the axilla. During the convulsion there was tremor of the lower limbs and his whole body was violently agitated by the powerful clonic contractions of his left arm which was strongly flexed, the fist being clenched. The head was turned to the left side, as were also the eyes; the mouth worked spasmodically, the teeth being gnashed together and the left corner of the mouth being drawn upwards. After he was restored to consciousness I directed his head to be shaved, cold to be applied to the vertex, a five-grain dose of calomel to be administered, and the patient to be kept as quiet as possible. Towards evening the convulsions recurred and the patient again lost consciousness. I consequently decided to operate, expecting to find an abscess beneath the site of the former injury.

At 9 A.M. on March 15th, the scalp having been shaved and washed with antiseptic solution of carbolic acid, I administered a hypodermic injection of half a grain of morphine, and my friend Dr. Moroura anæsthetised the patient with chloroform, which was well taken. Raising the scalp by a horseshoe flap, including the cicatrix, I found the scalp tissues and the pericranium strongly adherent to the

Digitized by Google

bone by fibrous bands beneath the old scar. Exposing the bone with the raspatory, a crown was removed by means of the trephine and elevator. The dura mater bulged somewhat into the aperture, but was not congested. On incising the dura mater and raising a flap the brain was found to be of normal appearance. I punctured it first with the needle of a hypodermic syringe and then several times with an aspirating needle, using the greatest care to pass the needle gently and perpendicularly to the brain surface. No collection of pus having been found the wound was washed with a solution of corrosive sublimate 1 in 2000, closed (drainage being allowed for by threads of catgut projecting from the posterior angle), and dressed with iodoform and boric acid lint. The crown of bone which had been placed in a warm solution of corrosive sublimate was not replaced, the signs of intra-cranial tension being so marked. During the course of the operation, whilst the patient was not fully under the influence of the anæsthetic, the convulsion recurred four times with great violence, retarding proceedings considerably; but when fully under the anæsthetic he lay quite quietly, breathing heavily. Each convulsion was preceded by a distinct aura, during which the respiration became shallow, the eyes were fixed, and the patient appeared to be gathering himself together prior to the approaching nerve-storm. During one of these attacks the tongue was severely bitten, a portion 2 in. in length of the left side of the tongue being almost severed; this I sutured and I kept the teeth apart with a gag.

Consciousness did not return after the operation and the patient was put to bed. The convulsions appeared to be of shorter duration; they came on with great regularity as before, at intervals of from fifteen to twenty minutes and lasting for about half a minute, the patient being perfectly unconscious during the intervals. After the administration of the chloroform the pupils were contracted. A large rectal injection of oil, soap, and water was ordered, which brought away considerable fæcal matter, after which two drachms of bromide of potassium dissolved in 4 oz. of water were injected per rectum and retained. The patient never recovered consciousness, and died the same night about 10 P.M.

On the following day I performed a necropsy. On removing the cranium the veins of the dura mater were found to be somewhat congested. The dura mater was easily removed from the subjacent membranes except at one point where the membranes were adherent and thickened over a surface of 1⅛ in. in length by ⅝ in. in width. This surface overlay the bases of the superior and middle frontal convolutions of the right cerebral hemisphere. The inferior frontal convolution on the same side was not involved. The above surface marked out the limits of a tumour about ¼ in. in thickness and apparently taking origin from the dura mater. On further examination of the brain substance there was no sign of meningitis, accumulation of pus, or hæmorrhage. The punctures into the brain substance made at the time of operation had entered the right middle frontal convolution.

The remarkable points about the above case are four. 1. The rapid onset of acute symptoms when a period of more than two months had elapsed since the injury. 2. The marked relief to intra-cranial tension which followed on bleeding from the arm. 3. The difficulty of making an exact diagnosis of the intra-cranial lesion, all the symptoms before operation appearing to indicate abscess. 4. The difficulty of localising the lesion by means of the characters of the convulsion, the motor disturbance indicating irritation of the ascending frontal and parietal convolutions rather than of the bases of the middle and superior frontal convolutions.

Wailuku, Maui, Hawaiian Islands.

UNIVERSITY COLLEGE, BRISTOL.—The annual meeting of the governors of University College, Bristol, was held on Nov. 16th, under the presidency of Mr. Lewis Fry, M.P. The report stated that the total number of students in attendance had been 525, of whom 90 had entered the courses of the Faculty of Medicine. Mr. Albert Fry, in moving the adoption of the report, stated that the College urgently required more funds. Mr. Bryant, F.R.C.S., in supporting the resolution, regretted the indebtedness of the College and added that he hoped that in time a university would be established in Bristol which would become an educational centre for that part of England. The resolution was carried unanimously.

VESICO-VAGINAL SEPTUM TORN DURING LABOUR; SLOUGHING VAGINITIS; SUBSEQUENT CLOSURE OF THE VULVA.

BY THOMAS WILSON, M.D., B.S. LOND., F.R.C.S. ENG.,
ASSISTANT OBSTETRIC OFFICER TO THE GENERAL HOSPITAL, BIRMINGHAM; LATE HONORARY GYNÆCOLOGIST TO THE WOLVERHAMPTON AND SOUTH STAFFORDSHIRE GENERAL HOSPITAL.

INDIRECT operative treatment of vesico-vaginal fistula may be carried out in two ways—by closure of the vagina or of the vulva. Of these the former is to be preferred whenever possible, but in the following case this would have been useless because of the partial destruction of the urethra and neck of the bladder. Closure of the vulva or episiorrhaphy was done by Vidal de Cassis, who freshened the labia majora; and Fritsch suggested that the freshening in these cases should be done by a process of flap-splitting, but I am not aware that there is any account of a similar procedure to that carried out in this case previously on record as having been carried into practice.

A young woman, aged eighteen years, was admitted to the Wolverhampton and South Staffordshire General Hospital on May 19th, 1892, having been ill since her confinement nine days previously. The labour only lasted six hours. The child was large, was born dead, and there appeared to the mother of the patient to be nothing unusual until after the labour was finished, when the urine dribbled away. The patient was attended by a midwife and only knew that she had had a good deal of headache and smarting in the front passage. On the seventh day Mr. A. Hands was called in for the first time, and on his recommendation the patient was sent into hospital. On admission the girl was found to be acutely ill, very weak and pale, but well nourished. There were slight dyspnœa and frequent loose cough with pale, frothy sputum. The tongue was dry and the breath had a strong, offensively sweet odour. The temperature was 102·2° F. and the pulse was 130 and feeble. A hurried examination showed no abnormal signs in the heart or lungs; the abdomen was prominent, but no tenderness or localised swelling or resistance could be made out. The perineum was split back to the edge of the sphincter and the whole vulvar region was much swollen, brawny, and red, the raw surface being covered with a putrid, stinking, whitish slough or false membrane; the urine constantly dribbled over the raw surface. On the following day the condition, local and general, remained the same and in the afternoon chloroform was administered and a careful examination made, the vagina being first flushed out with a gallon of very hot water. The floor of the urethra was wanting, the bladder and vagina forming one large cavity, at the upper end of which posteriorly was felt what was taken to be the partly closed cervix, on the right of which was another cavity into which the vaginal tube readily passed. The whole of the walls of this large irregular cavity were swollen, hard, brawny, and as much as could be seen was covered with the dirty white sloughy material above mentioned. The rectum was intact. The uterus could not be distinguished, and at any rate did not extend above the pubes. The interior of the cavity was scraped with a sharp spoon, glycerine with carbolic acid was swabbed over the surface, and a plug of gauze was introduced. The patient remained in a very critical condition for a week after this attempt at cleansing, the temperature ranging from 100·6° to 103·6°, and the pulse from 120 to 140, but she took four pints of milk and two eggs daily, and brandy freely, 16 oz. in the twenty-four hours for five days. For the following fortnight she continued steadily but slowly to improve and by June 9th the sloughs were all away, and the temperature had become normal in the mornings, but still rose to about 100° in the evenings; all the urine still dribbled away, and the exact local condition could not yet be made out. From June 22nd to 29th, without any apparent cause, the patient again became more febrile, the temperature varying from 100° to 102°, and the general condition being less satisfactory, but nothing locally could be discovered except some tenderness in the region of the right iliac crest. From the 29th the temperature remained

Digitized by Google

normal and on July 11th the girl was transferred from the infectious block to the general ward, having been up and about for a week and seeming strong and well. There was little, if any, vaginal discharge, but no control over the urine. On the 19th, under ether, the vagina was found to be considerably contracted and its walls were hard and resistant; the urethral floor had disappeared and its upper wall was adherent to the pubes and formed the upper boundary of the urethro-vaginal orifice. The wall of the rectum and the external sphincter were intact. The base of the bladder had almost entirely disappeared; in the hard roof of the irregular vesico-vaginal cavity an offset which admitted the index finger went upwards and to the right behind the pubes. The vagina admitted the forefinger for 2 in., and at the further extremity there were two offsets, one, the orifice of which felt like a dimple, into which a sound passed easily, going upwards and backwards for 1½ in.; and to the left of this a larger but shallower offset. No trace of the cervix uteri could be felt, and neither by vaginal nor rectal examination could anything be found resembling the uterus distinct from the hard walls of the irregular cavity just described. On August 8th, under ether, an attempt was made to close the orifice of the vagina while re-forming the urethra. A V-shaped incision was made with scissors round the orifice about ¾ in. deep except anteriorly, where a short longitudinal incision was made on either side; these short incisions enabled the urethra to be re-formed and the margins were united with silkworm gut sutures. The flap made by the V-shaped incision was then turned inwards, but with great difficulty, on account of the dense cicatricial resistance, and united with two strong wire sutures. On August 11th, three days later, a note was made that the urine still mostly dribbled, but 10 oz. had been passed on one occasion. On the 16th the urine was being passed in quantities of about 6 oz., and in the previous two days was only passed involuntarily on one occasion. One wire suture was removed on the 26th and the patient was allowed to get up on the 30th. On Sept. 3rd the last suture was removed and the parts had all healed satisfactorily, the vagina being completely closed, and a urethra of somewhat above the normal size having been formed. The patient could retain her urine for two hours or so when standing or walking, but if she went longer there was still occasional dribbling, though not to a great extent. On August 29th and 30th, and again from Sept. 29th to Oct. 2nd, the urine was discoloured with menstrual discharge. On Oct. 7th the patient was sent home and she was again seen in the out-patient room on Nov. 18th, well, and with complete control over the bladder.

Mr. Arthur Hands very kindly visited this patient for me in April, 1894, and finding that she had been married at the preceding Christmas he was good enough at my request to send her to see me. On April 24th she appeared well and healthy; she had returned to her work one month after leaving hospital and had continued till the last three weeks, when she left at her husband's request. The periods have appeared regularly every month, lasting three days or so; they are painless; the fluid passes in the urine, which becomes a little red. There are no clots. The patient would not know she was "poorly" if she did not examine her urine. The urine can be retained for three or four hours in the daytime and seven or eight hours at night; it is never passed involuntarily even in sleep. Since her marriage there has been no pain or difficulty in connexion and the sexual feeling is the same in all respects as before her child was born. There is now a thick, soft, fleshy perineum; the index finger passes easily along the canal which was intended for a urethra into a *oul-de-sac* lined with soft mucous membrane, partly divided into two by a septum, in front and above which, between it and the pubes, the examining finger passes into the freely communicating bladder; this anterior part is very tender to examination. Nothing that feels like a sphincter to the bladder can be made out. No opening can be felt in the wall of the posterior part of the *oul-de-sac*. Bimanually the fingers meet behind the pubes and at the sides and nothing definite can be made out. Per rectum, through the anterior wall is felt a firm, tightly fixed body, rounded from side to side with the convexity backwards, extending from immediately above the sphincter ani internus upwards for about 3 in.; nothing further can be made out by bimanual examination with the finger in the rectum.

What happened at the delivery of this girl will never be exactly known, the only certain facts being that there was a dead child born after a short first labour, that there was complete incontinence of urine from the time the labour was finished, and that on the seventh day the patient was in a gravely septicæmic condition with sloughing vaginitis, the result of urine flowing freely over the raw torn surfaces of the parturient canal. Her recovery from the grave condition she was in when admitted to the hospital is a striking instance of the value of alcohol in treating septicæmic conditions. Sixteen ounces of brandy daily for five days is a large dose for a girl of eighteen years; still, not only did this produce no sign of alcoholism, but it enabled her to take and digest a sufficient quantity of milk and eggs to satisfy our minds that it was acting as a tonic as well as a stimulant. The condition of the parts locally was such as to preclude a thorough cleansing of the surfaces, and we had to be contented with a partial cleansing, followed by repeated douchings.

After the recovery of the girl the injury was found to be too extensive to hope to restore the bladder, and as the urethral floor was also wanting some method had to be devised by which, if possible, a new sphincter could be provided. There seemed to be no way of testing the natural condition, nor did it appear to be worth while troubling too much about this since it was not clear whether any—or, if any, how much—of the uterus was left. The best way appeared on consideration to be that which was carried out with complete and permanent success—to split flaps by a V-shaped incision round the vulvar orifice, extending forwards as far as the level of the urethral floor, with two incisions at this level at right angles to the rest of the incision; by then bringing the raw surfaces together it was hoped to restore the muscular wall of the urethra at least sufficiently to get some power of retaining urine. The measure of success obtained was most gratifying. After the vulva was thus closed the uterus, as has often happened after colpocleisis for extensive vesico-vaginal fistula, gave evidence of its being still present by menstruation recommencing and continuing regularly. Since leaving the hospital the patient's general health has continued perfect and her marriage appears to have afforded complete satisfaction to herself and her husband, the repaired urethra having added to its functions without difficulty and with perfect success. The total absence of any irritation of the lining membrane of the bladder, or rather the new urine reservoir, and of any phosphatic deposit or subjective discomfort are notable facts, as also is the comfort with which the menstrual function is carried on under the new conditions. *A priori* some troublesome symptoms relating to these functions might be expected, and as a matter of experience in some of the cases in which the vagina has been thrown into the bladder vesical catarrh, metritis, pyelonephritis, or phosphatic calculi have been observed, but in the majority of subjects, as in the present instance, the different functions are continued in comfort.

LONDON LOCK HOSPITAL.

A CASE OF ACUTE PEMPHIGUS; RECOVERY.

(Under the care of Mr. BUXTON SHILLITOE.)

IT is very probable that several distinct forms of bullous disease of the skin are classed together under the name of pemphigus. It is at all events certain that in a large number of cases of bullous dermatitis a very definite micro-organism has been repeatedly found, while it is apparently not discoverable in all. When constitutional symptoms appear they are probably to be attributed to the absorption of toxins from a secondary streptococcic infection of the serum of the bullæ. We are not told in the record of the

Digitized by Google

case below in what doses the arsenic was administered, and therefore it is difficult to be sure that this was an instance of pemphigus in which arsenic failed. The diagnosis of a bullous syphilide from pemphigus is sometimes very difficult, but on the whole a true pemphigus is more liable to be mistaken for a syphilide than for the reverse error to occur. For the notes of the case we are indebted to Mr. C. F. Marshall, resident medical officer.

The following case was sent to the Lock Hospital as there was a suspicion of its being syphilitic in origin. The patient, a girl aged nineteen years, had no other signs of syphilis and the progress of the case without any specific treatment shows that it was not a bullous syphilide. The rash appeared on Jan. 1st in the form of clear blebs on a slightly reddened base, first on the hips and arms; afterwards it spread over the whole of the lower limbs, the greater part of the back, neck, forearms, and slightly on the chest and chin. The front of the abdomen, the palms of the hands, the soles of the feet, and the mucous membrane of the mouth were free. The bullæ varied in size from that of a pea to that of a walnut; they contained clear fluid at first but in a few days this became purulent and in some cases slightly hæmorrhagic. They soon coalesced when close together, forming large areas of sodden epithelium with sero-purulent discharge, but at no time were there any constitutional symptoms. The progress of the case is briefly as follows. By the 25th most of the bullæ had burst and coalesced; a few fresh ones were appearing from day to day; some were clear and others were purulent from the first when appearing on parts already affected. By Feb. 2nd the bullæ were nearly all healed, leaving a brownish-red staining of the skin. Some fresh pustules had appeared on the inner side of the thighs. The stains were mostly confluent on the back and limbs and were discrete on the neck. On the 24th the patient was sent away to the country. Only a few small blebs had appeared from time to time. Her general health was good. On March 11th there was a recurrence of fresh bullæ and pustules on the thighs, arms, and chin. These increased on the lower limbs till the condition was nearly as bad as at first. By the 23rd the skin was quite clear again except for fresh staining. On the 29th some fresh pustules appeared on the thighs, forearms, and face. On April 6th she was sent to the seaside, but a few days later, the 10th, she had another relapse. Clear bullæ appeared as at first, involving the whole of both upper and lower limbs, and slightly affecting the shoulders and chin. By May 2nd the skin was quite clear again and the general health was much improved. On the 15th a few small pustules appeared about the wrists and ankles. The stains of the old rash were fading. By June 1st she was well and no subsequent relapse has occurred. With regard to treatment arsenic was given internally nearly all through the illness, but it did not seem to have much effect. Locally the most satisfactory result was obtained from iodine baths (about 1 in 5000), which were given daily while the eruption was active. During the last severe relapse (April 10th) the local treatment consisted of liquor carbonis detergens, which acted equally well.

Bacteriological examination.—This was carried out by Dr. Bulloch at the British Institute of Preventive Medicine and we are indebted to him for the following notes:—Examination of fluid from the clear bullæ showed the presence of a diplococcus agreeing in almost every particular with the diplococcus first found by Demme in cases of pemphigus, and also found by Dr. Bulloch in other cases of acute pemphigus. Fluid from the bullæ which marked the relapse of April 10th was also examined, but the diplococcus was not present in this, only streptococci and staphylococci.

Remarks by Mr. BUXTON SHILLITOE.—This case is remarkable chiefly on account of recovery after such a severe attack of pemphigus and also for the total absence of constitutional symptoms. It is also of interest that a diplococcus was found by Dr. Bulloch agreeing with that found by Demme in similar cases. A further point is the fact that a month before the appearance of the rash superficial whitlows formed on several of the fingers. This is of interest in that Mr. George Pernet[1] collected several cases of pemphigus in butchers all of which were preceded by whitlows, suggesting the possibility of the poison being contained in the meat. In the present case there was no distinct history of contamination from meat except that the patient frequently did cooking. With regard to treatment I should like to draw attention to the benefit derived from local antiseptic treatment of the skin both by iodine and by liquor carbonis detergens, and to the apparent failure of arsenic to modify the course of the disease. I am much indebted to Dr. Bulloch for making the bacteriological examination and also to Dr. Roberts of the Folkestone Hospital for notes of the case during the relapse.

LIVERPOOL ROYAL INFIRMARY.

TWO CASES OF OMENTAL UMBILICAL HERNIA ATTENDED BY SLOUGHING.

(Under the care of Mr. RUSHTON PARKER.)

SLOUGHING of the skin over an umbilical hernia is a rare occurrence and even for that reason Mr. Rushton Parker's two cases deserve to be recorded, but there are other points of interest about them. In the first case the ulcer left after the separation of the slough healed rapidly with very little treatment. In the second the connexion between the interference with the circulation in the hernia and the two confinements is interesting, though easily explicable by the increased abdominal pressure. Mr. Parker's explanation of the manner in which the sloughing was brought about appears to be extremely probable.

CASE 1.—A woman, aged thirty-nine years, was admitted into the Liverpool Royal Infirmary on July 5th, 1880, having an umbilical hernia which was 2 or 3 inches in diameter and over which a small piece of skin had sloughed. After separation there was exposed œdematous and juicy connective tissue of a pale greenish colour, suggesting bile-staining. An offer of herniotomy was made to the patient for the purpose of curing the rupture, but this she declined. The exposed tissues healed without difficulty or complication under some antiseptic dressing. The rupture had given her no inconvenience until the slough appeared, and when the aperture closed over her purpose was served and she left the hospital after a few weeks. The contents of the sac were apparently omentum, but were never seen.

CASE 2.—A woman, aged forty-two years, was sent to Mr. Rushton Parker's ward at the Liverpool Royal Infirmary on the night of May 1st, 1891, by Dr. Henry Briggs, who informed Mr. Parker that he had found her in a feverish condition with an umbilical hernia in a state of acute inflammation, with sloughing of the skin over the sac, which evidently required operative treatment without delay. Mr. Parker therefore went up to the ward about midnight and learnt that the hernia was an old one; that the patient had been confined eighteen months previously, after which the hernia had become discoloured and had remained so; that three weeks before admission she had also been confined; and that the hernia had become acutely inflamed. An operation was performed at once under chloroform, the hernia being of about the size of a man's fist, surrounded by an acutely inflamed area and having a black skin slough in its centre somewhat larger than a crown piece. The sac was laid open and was found to contain extremely fœtid pus and gangrenous omentum. The skin slough was cut away and the interior was well washed with a 1 in 1000 solution of perchloride of mercury. The neck of the sac appearing to be free from contamination the omentum was pulled out and transfixed with two large pins, behind which it was tightly tied with a piece of strong bandage soaked in the sublimate solution of the strength above mentioned. All the gangrenous portion was cut away and with it the anterior portion of the sac, which was also gangrenous. The wound was left open and filled with iodoform gauze. Some more sloughs separated in the course of about ten days and healing was gradually accomplished without local incident or complication by the last day of June, two months after admission, the site of the former hernia being well depressed. The temperature at the time of the operation was over 102° F., but fell during the early morning to normal and remained so for three weeks except for a rise of a single degree on the fourth day. Then the temperature rose to 100° but fell to normal for a day and a half, then rising again to 100°. In the middle of the fourth week there was an evening rise to nearly 105°, but the temperature fell a degree each evening and at the end of the fourth week the normal was again reached and so remained during the fifth week. The temperature in the morning was 3° or 4° lower than in the evening during this rise. The sixth week commenced with

Digitized by Google

another evening rise to 105° and the fever continued for three days, the temperature being 1° lower each evening and being about 100° each morning. After a day's remission the temperature rose to 103° and 102° for three more days and finally dropped. No certain explanation of these feverish attacks was ascertained. The pulse was 120 and bounding, the tongue was dry but not coated, and there was thirst. But the contracting and healing wound showed neither suppuration nor retention; nor was there any abdominal tenderness. The fever may have been due to constipation which was relieved by glycerine enemata.

Remarks by Mr. RUSHTON PARKER.—In Case 1 I was puzzled at the time to account for the sloughing, and apparently had an idea then that there must have been a small fæcal fistula. The case is merely catalogued and the following words are appended: "Sloughing skin and fæcal fistula." But I cannot now remember whether this fistula was an observed fact or only, as I rather suppose, a mere inference from the biliary staining beneath the slough. In any case the wound healed very simply. The question arises, How did the sloughing and inflammation start in Case 2? I am inclined to attribute it to, first of all, sloughing of the skin from stretching, probably during the efforts of parturition. Then followed infection of the adjacent parts, of the sac, and eventually of the contained omentum. The bacterial invasion must have come either from the intestine or from the skin. There is no evidence that it came from the intestine, which never came into the case at all, much less gave any suggestion of a fæcal fistula. It can easily be accounted for by the pressure and stretching of the skin of the over-distended sac on the over-distended abdomen at the end of pregnancy. The occurrence of this case seemed thus explained at the time. Moreover, it appeared to me also to throw light on the previous case, which I am inclined to regard as a milder form of the same accident.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Hip-joint Disease.—Exhibition of Specimens.

A MEETING of this society was held on Nov. 22nd, the President, Mr. BRYANT, being in the chair.

Mr. EDMUND OWEN read a paper on a Distinct Variety of Hip-joint Disease in Children and Young Persons. He drew attention to a very important group of cases of acute suppurative disease of the hip-joint which must be carefully separated from the much more common tuberculous disease of this joint. The disease was caused by the invasion by the micro-organisms of osteomyelitis of the very active tissue at the upper extremity of the diaphysis of the femur. Reference was made to the fact that the hip-joint differed from all other joints in that the end of a diaphysis entered into its formation, and that, therefore, when this diaphysis was the seat of osteomyelitis suppurative arthritis almost inevitably resulted. The symptoms of this form of disease were especially characterised by sudden onset, acute course, and intense severity. There was often a history of injury or some lowering disease preceding the onset of the attack, and it was suggested that such conditions, by lowering the vitality of the growing tissue, render it more vulnerable to infective organisms. Death from septicæmia was liable to occur if the disease was not speedily recognised and adequately treated. The treatment advocated was the free opening of the joint, with removal of the epiphysis and the affected part of the diaphysis, and the thorough application of germicides to the interior of the joint, and this operation must be followed by drainage. In view of the urgency of these cases Mr. Owen laid stress on the extreme importance of early correct diagnosis and immediate efficient treatment. He concluded with the report of four illustrative cases under his care. Reference was made to a paper on this disease by the late Dr. J. S. Bristowe, published in the Transactions of the Pathological Society for 1862.

Mr. A. E. BARKER called attention to the fact that the paper described a condition which was well recognised and emphasised the very important point that in osteomyelitis affecting the hip-joint active measures must be promptly resorted to and carried out. The treatment which in acute tuberculous disease of the hip-joint he had advocated some years ago, and which he now was glad to see Mr. Owen fully endorsed—viz., the clearing out of the joint and closing of the wound—would in the cases described by Mr. Owen lead to disastrous results. He referred to one class of case in which such a procedure was advisable and had been successfully carried out by himself—viz., in the case of gonorrhœal infection of the hip-joint. He did not agree with Mr. Owen that strong germicidal solutions were necessary for washing out the joint, but considered that thorough washing with an indifferent fluid was most effectual and did not give rise to the destruction of tissue which arose from the use of strong mercurial solutions.

Mr. W. G. SPENCER drew attention to the fact that the disease as described by Mr. Owen as septic disease of the upper end of the diaphysis of the femur was the same as epiphysitis and acute periostitis of the upper end of the shaft. The fact that the diaphysis entered into the formation of the hip-joint did not, he considered, make so essential a difference in the affection of this joint as Mr. Owen in his paper seemed to infer, for in 3 cases under his care in which the disease was situated in the diaphysis the joint contained pus; in the first of these the upper end of the humerus was affected, in the second the lower end of the femur, and in the third the upper end of the femur. He could not agree with Mr. Owen's radical procedure of removing the head of the femur, but thought that the more conservative process of washing out the joint and drilling into the diaphysis was often attended with good issue, and in this manner the results of thrombosis of the Haversian canals migh tbe relieved, and the head of the femur be preserved. He was always in such cases accustomed to use a strong germicide solution, and he preferred carbolic lotion to perchloride of mercury owing to its less poisonous character.

Mr. WARRINGTON HAWARD said that the special treatment advocated in Mr. Owen's paper was necessary in this acute form of hip disease in order to save the life of the patient; a treatment less radical did not remove the seat of the disease, and therefore it was essential to remove the head of the femur and the diaphysis. The treatment of simply washing out the joint did not remove the original seat of the disease and jeopardised the life of the patient.

Mr. F. C. WALLIS reminded the society that he had shown a case of somewhat similar nature at the Clinical Society, a child, two years of age, in whom after an accident an abdominal swelling appeared associated with pain in the leg. On opening the abscess in the abdomen three-quarters of a pint of pus were evacuated and the head of the femur was found loose in the abscess cavity. The child made a good recovery.

Mr. GOLDING-BIRD differed from Mr. Owen with regard to the removal of the head of the bone. He did not himself think it necessary in all cases which were of a fulminating nature and the following case which had come under his care proved that recovery might take place without such a procedure. A boy, aged eight and a half years, fell on his hip. The next day he limped and on the following day he was so ill that he was brought to the hospital, the diagnosis then made being acute septic inflammation of the hip. On the following day an incision was made over the hip-joint and pus was evacuated from the joint. No evidence of any bone disease could be detected. The joint was accordingly washed out and the wound closed with the exception of a small gauze drain, after which the boy made an uninterrupted recovery. Either the case belonged to a group distinct from that described by Mr. Owen or the radical procedure advocated in Mr. Owen's paper was not always necessary. In the former case it was difficult to see how such a case could be distinguished clinically from those cited by Mr. Owen.

Dr. STUART MACDONALD cited a case of a boy, aged sixteen years, whose illness had lasted seven days. He had pain and swelling in the upper part of the thigh. An abscess was opened and the joint appeared to be normal and no further operation was carried out. The boy, however, died on the following day and at the necropsy it was found that the joint contained 2 drachms of pus and the whole body showed signs of general pyæmic infection. On making a section through the head of the femur no evidence of any inflammation along the epiphysis could be found, though there was some thickening and separation of the periosteum about the neck of the bone. In some of these cases when the disease began in the periosteum recovery might result from simple irrigation of the joint.

The PRESIDENT remarked that some years ago he wrote a

Digitized by Google

paper on pyæmia and that he had pointed out that the cases of what he had called "acute ostitis" were the most typical cases of advanced pyæmia associated with purulent pericarditis and with abscesses in the tongue. He related a case of infection of the hip-joint of six days' duration in which after evacuating the pus from the joint, he drilled the neck of the bone and let out a sero-purulent fluid. The patient recovered. He could not therefore follow the strong opinion expressed by Mr. Owen that it was necessary to use freely the gouge, the scoop, and germicides. He insisted that the process of drilling the bone should not be omitted.

Mr. OWEN, in reply, thought that the term "acute ostitis," as suggested by the President, might be used with advantage, but even that was likely to be misunderstood and misused. He said that he was not in favour of excision in early tuberculous disease of the hip-joint, as Mr. Barker seemed to suggest. He was of opinion that the disease did not begin in the epiphysis, but started in the end of the diaphysis. He had possibly, as suggested by Mr. Spencer, somewhat exaggerated the importance of the situation of the diaphysis in the hip-joint with regard to the occurrence of suppuration in the joint. He was of the opinion that the case quoted by Mr. Golding-Bird was one of acute purulent synovitis and not a case of the variety which he had described in his paper.

Mr. T. LYNN THOMAS exhibited two specimens of (1) Excision of Traumatic Structure of the Urethra and (2) Excision of Goitre.

EPIDEMIOLOGICAL SOCIETY.

Sanitary Progress and its Results.

A MEETING of this society was held on Nov. 18th, the President, Dr. H. F. PARSONS, being in the chair.

The PRESIDENT delivered the Inaugural Address of the Session 1898-99, on Half a Century of Sanitary Progress and its Results. It was, he said, just fifty years since the passing of the first general Public Health Act, and the last published report of the Registrar-General was the fiftieth since the classification of causes of death had been carried out uninterruptedly. In 1844-45 the Health of Towns Commission issued reports on the sanitary conditions of what were then the fifty largest towns in the kingdom, and the state of things therein described was almost incredible. The poor lived in slums such as were now rarely to be seen, cesspits were universal, and often within the houses, pipe-drains were unknown, and flat-bottomed, pervious brick drains for the carriage of slop waters were confined to the best streets, open gutters receiving the filth elsewhere; traps did not exist and the air of streets and houses alike was poisoned with stenches; the water-supply was drawn from polluted wells or from rivers without filtration and stored in open butts, &c.; and filth of every kind was accumulated in middens and laystalls in the most crowded quarters. Fevers were rampant and consumption decimated the population, while the condition of the rural districts was little if at all better. In 1838-42 the average death-rate was 22·1 per 1000, of which 4 per cent. were due to fevers, and in 1847-50 it was 23·4 per 1000, that from fevers being 5·3 per cent. On the other hand in 1891-96 the death-rate was 18·1, with 1 per cent. only due to fevers. In London the mortality from fevers had sunk from 1·339 per 1000 inhabitants in 1838-40 to 0·142 in 1891-96, or one-tenth of the former rate. Some of this improvement was doubtless due to the better social conditions of the people, for, as Lord Macaulay in his history published in 1848 pointed out, instead of one person in 40, one in 23 died every year in London in the time of Charles II., and since he wrote this wages had risen, the food of the working classes had improved, the consumption of meat had increased enormously, while the greater facilities for intercommunication and migration had tended to equalise the labour market so that since the cotton famine in the early sixties there had been no widespread distress sufficient to affect the public health, and the proportion of persons in receipt of Poor-law relief had been reduced from 57 per 1000 in 1849-51 to 23·4 in 1892-6. It was impossible, too, to ignore the progress of medicine and surgery, especially the antiseptic treatment of wounds, which had greatly lessened the fatality of accidents incident to the extension of machinery into every industry. On the other hand, there were conditions tending in the contrary direction, such as the aggregation of the population in towns. The proportion of persons resident in urban districts to 100 in rural had risen from 100 in 1851 to 212 in 1881 and 258 in 1891; and at the last census the number of persons resident exceeded those born—in London, by 18 per cent. in Lancashire by 19, and in Glamorgan by 42. In purely rural districts the reverse proportion was met with, the persons throughout the country born in Huntingdonshire exceeded the population of that county by 38 per cent. This migration to towns tended to a higher death-rate, the comparative mortality of the agricultural labourer being the lowest of all among the working classes, the death-rate during the last ten years having been 19·5 in the town as against 16·9 in the country districts, or if corrected for age and sex 22·32 and 16·95 respectively; while the density of population throughout the country had risen from 325 per square mile in 1851 to 527 in 1896, the increase being, of course, much greater in the towns and in industrial districts. Dense population tended to raise the death-rate, especially from infectious diseases, the spread of which was also favoured since 1870 by compulsory school attendance. The first general Public Health Act was passed in 1848, the year following the earliest attempt at legislative control of water-supplies. It was based on the recommendations of the Royal Commissioners and dealt with most of the matters covered by subsequent Acts, though infectious diseases received but scant attention, and it was to a great extent partial and optional in its application. The General Board of Health which was then created did noble work, but being considered in advance of public opinion was abolished in 1854, its functions being relegated to the Privy Council and Home Office until, in 1871, they were transferred to the newly constituted Local Government Board and the sanitary authorities. The sanitary authorities experienced changes, not always for the better, under the Local Government Act of 1888; though the creation of the county councils, especially when they appointed county medical officers of health, led to better control of the rural districts. The Sanitary Acts of 1855, 1866, 1872, and the Public Health Act of 1875—a codification of the preceding, further amended and strengthened by the Public Health Amendment Act of 1890—the Infectious Diseases Acts of 1889 and 1890, and those for the Housing of the Working Classes of 1868 and 1875 amalgamated by that of 1890, and lastly the Public Health Act for London of 1891, had brought the sanitary administration of the country to its present state of efficiency. The Vaccination Act of the present year was, however, a retrograde step, and the defaults, who had risen from 4 or 5 per cent. of infants born twenty years ago to 20 per cent. in 1894, would probably soon amount to a majority. Sewerage was now almost universal in towns and the drainage of houses was yearly becoming more satisfactory, though the question of the disposal of sewage was still unsettled, various methods being employed more or less provisionally. The health of towns was improving through better sanitation, opening up of thoroughfares and open spaces, new building regulations, the abolition of slums and the tendency to the erection of warehouses in the central parts, the displaced population migrating to suburban districts. Hospitals for isolation of infectious diseases were springing up everywhere, and were now willingly utilised by the parents of children not only of the poor but of the middle-classes.

The average annual death-rate had sunk from 23·1 in 1847-51 to 18·1 in 1892-96, with a saving on the population at the last census of 145,000 lives per annum; in the rural districts it had fallen from 19·9 to 16·7, and in the urban from 24·7 to 18·8. In the thirty-three largest towns it was now 20, scarcely more than in the country districts from 1851 to 1860. That this improvement was due to sanitary measures was evident from the fact that it began with the passing of the Public Health Act of 1872 and had been greater in each successive quinquennium, though for the twenty years 1851-71 it had been practically stationary. It was most marked in the zymotic class, the death-rate per 1,000,000 from continued fevers having fallen from 1184 to 184, that from scarlet fever from 1001 (in 1862-66) to 118 (in 1892-96). Typhus fever had almost disappeared, but diphtheria seemed to be increasing and there was unfortunately no great diminution in the general mortality of infants. A comparison of successive life tables showed that while the mean duration of life was greater by four years for males and six years for females fewer persons reached *extreme* old age, though more survived to or beyond middle life; and consequently cancer,

Digitized by Google

diabetes, and other diseases of advanced life appeared to be greatly on the increase. Enteric fever was most prevalent in the northern counties, where sanitation was less advanced and the "midden" still held its ground. Epidemics, like those at Maidstone, Newport, Worthing, and Kidderminster, caused by casual pollution of public water-supplies, occurred from time to time in various places. "Diarrhœa," though properly a symptom only and now often registered as enteritis, was in the form of infantile diarrhœa prevalent in the autumn under certain meteorological conditions. This was a specific disease and more confined to towns, the etiology of which deserved further study, as did the peculiar and changing distribution and prevalence of diphtheria. The remarkable reduction in the mortality from scarlet fever was to be ascribed rather to the lesser fatality which had marked it of late; for it was still very prevalent and in local outbreaks, amid grossly insanitary conditions, exhibited all its former virulence. After the widespread epidemic of small-pox in 1871–72 vaccination became general and small-pox had in consequence almost disappeared as a cause of death, especially in those towns where the cases were removed to hospitals beyond their borders; but the outbreaks at Leicester, Sheffield, Gloucester, and Middlesbrough, afforded indications of what we might expect from the abandonment of general vaccination. The last disease he would consider was tuberculosis, which in all its forms, with one exception, had shown a marked reduction, the mortality from phthisis being now less than half that which it was fifty years ago—a result attributable to the better drainage of land, the improved ventilation and sanitation of houses, factories, and workshops, and the higher standard of living and comfort now enjoyed by the mass of the people. The one exception was that of tabes mesenterica or the intestinal tuberculosis of infants, which was certainly to be attributed to the increasing use of the milk of cows, a large proportion of these animals suffering from tuberculosis. Such milk could be rendered innocuous by boiling or sterilisation; and attention having been called to the subject it might be hoped that steps would be taken to reduce, if not to stamp out, the disease in dairy farms. The discovery of the bacillus had fully explained the etiology of tuberculosis in every form, and could the public mind be brought to realise also the dangers arising from the diffusion of the dried sputa of phthisical persons the prevalence of this disease might be reduced to a point hitherto unhoped for or deemed beyond the possibility of attainment.

SOCIETY OF ANÆSTHETISTS.

Pure Anæsthetics.

A SPECIAL meeting was held on Nov. 17th at the society's rooms, 20, Hanover-square, W., the President, Dr. DUDLEY BUXTON, being in the chair. It was decided to alter the day of meeting from the third Thursday to the third Friday in each month. At the conclusion of the special meeting the first ordinary meeting of the present session was held.

The PRESIDENT in welcoming the members at the opening of the session urged upon them the necessity for individual effort in promoting the interests of the society.

Professor W. RAMSAY, F.R.S., read a paper on Pure Anæsthetics. He drew attention to the unpleasant effects produced by giving chloroform in the presence of lighted gas or lamps. The pungent odour affecting the eyes, nose, and throat was due to the formation of carbonyl chloride the result of burning chloroform vapour. The body was a gas at ordinary temperatures which condensed to a colourless liquid, and in the presence of moisture decomposed into carbonic acid and hydrochloric acid. Chloroform on exposure to sunlight or diffused daylight and to air undergoes decomposition with the formation of phosgene gas. The addition of alcohol prevented the formation of carbonyl chloride when moist air and light were excluded. Other impurities were practically eliminated by ordinary care in the manufacture. The best test of the presence of carbonyl chloride was, he thought, to breathe it when its irritant action on the throat revealed its presence. To remove this impurity agitating the suspected chloroform with slaked lime proved effectual. The chloroform was then filtered off. Professor Ramsay quoted statistics, collected by Dr. Newman of Glasgow, which showed that the use of chloroform thus purified lessened the after-effects. Referring to ether, Professor Ramsay stated that a sticky residue, which was probably an ethyl peroxide, was liable to be formed in ether which had been exposed to light and air. To purify ether it was suggested that to shake it with metallic mercury was the most satisfactory method. The "A.C.E. mixture" had been investigated by Mr. Smiles for Professor Ramsay. He found that the presence of alcohol might be considered of no advantage while the percentage of chloroform in vapour rapidly increased until finally it was as much as 62 per cent.

Mr. WILLETT thought the test by smell was inadequate. He regarded the method adopted by Professor Ramsay in estimating the evaporation of the constituents of "A.C.E. mixture" as too dissimilar to what obtained when that mixture was employed clinically to carry much weight.

Dr. SILK referred to the different views held by anæsthetists with regard to what makes of chloroform and ether contained the least impurities and were therefore best for inhalation. He believed that methylated ether was as good as pure ether, but thought most opinions favoured the use of pure chloroform.

Dr. A. COOK contended that the "A.C.E. mixture" if given from a Rendle's mask was not evaporated in the irregular manner suggested by Professor Ramsay. He thought it possible that carbonyl chloride might be produced even without the presence of a flame and instanced a case in which an irritating vapour was given off from chloroform in the daytime.

Mr. MCCARDIE said he had been informed that some methylated spirit contained a certain amount of naphtha which might possibly account for some of the impurities of methylated ether, although his experience went to show that the methylated ether was as good clinically as pure ether.

Mr. CARTER BRAINE quoted two cases in which chloroform which had been exposed to air for a fortnight had caused great coughing and distress to the patient.

Dr. PROBYN-WILLIAMS had read of severe symptoms leading to death ensuing upon the administration of chloroform in the presence of lighted candles during a prolonged abdominal operation undertaken at night. His experience showed that methylated ether was in every way satisfactory.

Mr. E. F. WHITE corroborated this view. He thought it was a matter of importance to elicit whether ethers of different specific gravities differed in their clinical behaviours. Referring to Dr. Newman's results he thought the amount of sickness noted was excessive and more than was usual by the methods in use in England.

Dr. E. A. STARLING believed that the methylated chloroform and ether produced more after-effects than the pure anæsthetics. The A.C.E. mixture he considered to be unreliable, and his clinical experience bore out the experiments which Professor Ramsay had quoted.

The PRESIDENT, after thanking Professor Ramsay for his valuable paper, drew attention to the fact that impurities in chloroform and ether might be introduced during the process of manufacture or as a result of exposure. In the "Pictet" process, although an absolutely pure product was secured, yet it was largely diluted with added alcohol to maintain its purity, and was even then as liable to subsequent decomposition as other varieties. The same remark applied to the more modern methods of manufacture from the grey acetate of lime and by the chloral process.

Professor RAMSAY, in reply, believed that most of the reliable manufacturers turned out pure chloroform and ether. No naphtha impurities appeared in the methylated ether. The "Pictet" method was inferior to those depending upon fractional distillation for their purification.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—After-Treatment of Abdominal Section.—Combined Method of Pelvic Surgery.

A MEETING of this society was held on Nov. 10th, Dr. H. MACNAUGHTON-JONES, President, being in the chair.

Dr. J. MACPHERSON LAWRIE (Weymouth) showed (1) a large Broad Ligament Cyst and (2) Double Broad Ligament Cysts.

Dr. HERBERT SNOW resumed the adjourned discussion on Mr. Christopher Martin's paper on Some Moot Points in the After-Treatment of Cases of Abdominal Section. He held

Digitized by Google

that after-treatment was of more importance than the actual operation. Cleanliness and dryness were the cardinal points, and they were more important than antiseptics. As regards sutures he thought it important to secure the peritoneum separately, but it was often a waste of time to suture the fascia and skin separately. He agreed with Mr. Martin that silk was not reliable and that it might give rise to sinuses and sepsis. For purgation he preferred an enema at the end of forty-eight hours; after that morphia might be given if necessary. But he had a strong prejudice against the drug, especially as it increased the tendency to constipation.

Dr. C. H. F. ROUTH was an advocate of drainage in every case. He objected to iodoform for the wound, since it might give rise to poisoning by absorption. His plan was to dip cotton-wool in iodine and to apply it to the sides of the wound. He discountenanced morphia and considered that trional and paraldehyde were far better as they were sedatives without any injurious effect.

Dr. BANTOCK remarked that the paper was concerned with matters of detail on which there would always be room for divergences of opinion. He agreed with Mr. Martin on some points, such as the importance of dry dressings and the value of silkworm gut as a suture material. But on other points he disagreed, for instance on the question of posture and the administration of morphia. Why did Mr. Martin use iodoform and boric acid in septic cases? For his part he endorsed the dictum of Knowsley Thornton that it was no use employing antiseptics when the patient was herself septic. In the case of a healthy young subject the abdominal wound could quite well be closed in one layer, but in emaciated women separate layers were necessary, requiring buried sutures. Stitch abscesses were caused simply by tying sutures too tightly. His rule as to drainage was—when in doubt drain, for if unnecessary it could do no harm, whereas if not used when it ought to be the patient's doom was sealed in forty-eight hours.

Mr. BOWREMAN JESSETT agreed with Mr. Martin's views as to posture, but pointed out that moving must be carefully done and not by the patient, but by a skilled nurse. When drainage was used he thought the patient should be kept on her back. Formerly he sewed the wound in one layer with silkworm gut, and if all the tissues were included this often answered perfectly. But there was a risk of drawing up the peritoneum between the muscular layers. He now generally sewed up in three layers. He had abandoned silk and silkworm gut for buried sutures, and used instead catgut prepared according to the directions of Martin of Berlin. For the skin he used silk or horsehair. His rule about drainage was, like Dr. Bantock's—when in doubt drain. The administration of morphia must depend on the patient; it was generally indicated in neurotic cases. As to purgation, he generally got the bowels open on the second day.

Dr. PURCELL remarked that the preparation of the patient had a great deal to do with the after-treatment. The opening of the peritoneum was an important point; it was better to go not through the linea alba but through the rectus muscle. If a drainage-tube were used a loose suture should be put in and tied. He generally purged early, giving 5 gr. of calomel on the second day. He had once lost a patient through morphia and had given up its use.

Mr. CHARLES RYALL asked Mr. Martin why he waited till the fourth day before purging the patient. He saw no reason why an aperient should not be given on the night after operation.

Dr. TRAVERS thought the dressing was one of the most important things. He used a dusting-powder of chinosol and boric acid. Morphia should be given sparingly and in small doses—$\frac{1}{8}$ gr. was usually sufficient. For purgation he relied largely on calomel and did not give enemata if he could help it.

Dr. HEYWOOD SMITH was glad to hear favourable opinions about calomel. One of the most anxious symptoms after operation was flatulence, because the question always arose whether it was the precursor of peritonitis.

The PRESIDENT regarded the dorsal position after operation as most important and as anatomically indicated. He always sutured the wound in three layers, using silk for the peritoneum and fascia and silkworm-gut for the skin. He thought Mr. Martin went too far when he said that stitch abscesses should not occur in clean cases, but at the same time he did not agree with Dr. Bantock that they were due to sutures tied too tightly. He would say—when in doubt drain, for he thought that blood should not be left in the peritoneal cavity, even clean blood. He never gave morphia. For purgation he preferred sulphate of magnesia given on the second or third day in drachm doses every half hour or hour till the effect was produced.

Mr. CHRISTOPHER MARTIN briefly replied.

Mr. STANMORE BISHOP (Manchester) read a paper on the Combined Method in Pelvic Surgery, the discussion on which was postponed till the next meeting.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Cancer in Relation to the Dwelling.

A MEETING of this society was held on Nov. 11th, Dr. E. GWYNN, President, being in the chair.

Dr. W. H. SYMONS read a paper on Cancer in Relation to the Dwelling, a subject to which he said he had turned his attention since his appointment as medical officer of health of Bath, in the hope that the study of the vital statistics of a city notorious for its high mortality from cancer, and the population of which was exceptionally constituted, might throw some light on certain aspects of the etiology of cancer. For forty years the population of the borough had been stationary, amounting to about 52,000, of whom two-thirds were females. The proportion of persons over sixty-five years of age was 76, as against 45 in England and Wales, and of children under five years of age 89, instead of 123, per 1000 living; while that of persons living on their own means was 101, as against 36, Hastings only among towns in the southern counties having a like proportion. The health of the town was good and improving, the actual number of deaths being as follows:—

—	Standard fully corrected.	Mean, 1881-90.	Mean, 1891-5	1896.	1897.
All causes	1056	1043	931	921	361
Typhoid fever	12	5	3	5	3
Phthisis	94	38·5	73·2	61	64
Other respiratory diseases	377	361	345	300	308
Cancer	**42**	**53·8**	**57·4**	**62**	**65**

At the same time cancer had shown a steady increase until the deaths were 50 per cent. higher than they should be after correction for age and sex. In the English counties, great as were the differences in the crude and even the standard death-rates from cancer, the extremes fell between + 10 and − 10 per cent. if the population over thirty-five years of age were alone taken into account. Dr. E. N. Nason, Dr. T. W. Blake, and Dr. Lloyd Jones had endeavoured to establish a relation between the conditions of the habitations of a people and the prevalence of cancer, Dr. Nason maintaining its preference for low-lying, damp dwellings as Mr. Haviland had for places liable to floods; but the high death-rate of Shrewsbury could not be so explained since but a small part of the town was affected by the inundations. The city of Bath, situated in a deep valley traversed by a sluggish river, on a dense surface soil overlying lias and oolite, with ground-springs and hard water, and surrounded by steep, in some places precipitous, hills, from 300 ft. to 500 ft. in height, presented every variety of site. Some local practitioners believed in the existence of a "cancer zone," but he could find nothing in the distribution of the cases to support this opinion, though there were some peculiarities, as that of a street in which 13 deaths had occurred in ten years on one side and only one on the other. Neither the elevation nor the aspect nor the class of house seemed to have any constant relation to the incidence of the disease, while the fact that in the course of thirty years 4 deaths had never been known in the same house, 3 in six only, and 2 in very few, the vast majority being the only ones recorded, seemed conclusive against any hypothesis of the disease being influenced by the conditions of the dwelling.

Dr. NEWSHOLME believed the increase of cancer to be apparent rather than real, due to better diagnosis and certification. This view was supported by the fact that in insurance offices whose members were of a class able to

Digitized by Google

command skilled medical advice no such increase had been observed, nor was it so marked among women in whom the organs mostly affected were palpable, the increase being mainly in the cancers of the stomach, liver, &c., especially among men, which were formerly registered as "internal disease" or other vague designation. Street distribution resolved itself into social differences, and these involved those of mean age and therefore of liability to cancer. In comparing towns the presence of large hospitals must be considered and whether these were county hospitals or not, for the Registrar-General excluded the deaths of strangers in the case of the former only. The death-rate among persons over thirty-five years of age was dependent on the mean longevity of the classes to which they belonged; thus, among farmers over that age it was 23 per 1000 and among tailors 20 only, simply because fewer of the latter attained to the age at which cancer was most frequent.

Dr. HERBERT SNOW (present by invitation) maintained that all statistics dealing with cancer as one disease instead of a group of diseases having little in common were necessarily fallacious. There were in all predisposing and exciting causes. Thus, epithelioma commonly followed the mechanical irritation of an unhealthy mucous surface. Carcinoma, a glandular neoplasm, was in the female organs a deviation from the normal devolution or degeneration of the uterus or breast, when their functions ceased to be exercised, induced by previous excessive activity or other depressing influences. Heredity could be asserted of "blastomata" only and sarcomata differed essentially from the rest of the so-called cancers. Cancer was a disease of civilised life and was more frequent in domestic animals than among wild ones, and especially so in cows whose lives were most removed from a state of nature and who were subject to debilitating influences and local irritation.

Dr. SYMONS, in replying, remarked that while the large number of retired officers and elderly ladies in Bath would tend to the greater prevalence of cancer, the excess of females over males, as 150 to 100, and in Bathwick as 200 to 100, being chiefly due to the number of domestic servants, would have the opposite effect, they being largely drawn from the country, whither they returned if ill.

LIVERPOOL MEDICAL INSTITUTION.

Nutshell in the Larynx. — Exhibition of Radiographs.— Rupture of the Membranous Urethra.—The Open-air Treatment of Tuberculosis.

A MEETING of this society was held on Nov. 17th, Dr. MACFIE CAMPBELL, President, being in the chair.

Mr. MITCHELL BANKS read notes of a case of a Piece of Nutshell in the Larynx removed by tracheotomy from a girl aged seven years. The foreign body was seen by Dr. Hunt to lie immediately below the cords, the vocal cords being excoriated by its passage. The child had a severe attack of dyspnœa in the night and next day Mr. Banks performed tracheotomy and removed the foreign body.

Mr. BANKS also showed Radiographs of (1) a Bullet in the Foot and (2) a Bullet in the Thigh (photograph taken by Mr. C. T. Holland).

Dr. ALEXANDER described a case of Complete Rupture of the Membranous Urethra in a man, aged twenty-seven years, who was run over by a dray and sustained in addition a compound fracture of the right femur. A sac filled with blood and serum was found on perineal section in front of the bladder. This sac was at first mistaken for a ruptured bladder and drained. Next day the bladder was found, pushed far back at the pelvis, and completely separated from the urethra; it was opened by Cock's method. The bladder was drained by tube and the large sac by gauze. The necessary splints for the fractured thigh interfered somewhat with after treatment but the patient was going on well.—Mr. BANKS and Mr. RUSHTON PARKER spoke.

Dr. NATHAN RAW read a paper on the Open-Air Treatment of Tuberculosis in Sanatoria. He alluded to the general prevalence and high mortality from tuberculous disease, which, although diminished in recent years by improved sanitation and food inspection, still ranked too high. He mentioned the poor results of treatment in general hospitals and considered it unfair to both the patient and the other inmates of a general ward that he should be treated therein. He combated the "inheritance" of phthisis and insisted on its infectivity. He concluded by considering it the duty of the legislature to deal thoroughly with the question of cure in sanatoria, and urged municipalities, boards of guardians, &c., to establish sanatoria.—The PRESIDENT, after congratulating Dr. Raw upon the excellence of his paper, remarked that while by the tables shown the mortality from tuberculous disease in adults had enormously decreased Sir Richard Thorne had pointed out that the mortality from this cause under one year of age had increased—due, he thought, to the greater use of cow's milk at that age. A pure milk-supply became a necessity. Country milk brought into Liverpool had been shown by Dr. Hope to contain the bacillus of tubercle in 13 per cent., while milk from town shippons only contained it in 4 per cent. It was interesting to know that heating milk to 195° F. was sufficient to sterilise it.—Dr. HOPE emphasised the close identity between measures which had been successful in the prevention of tuberculosis and measures which promised to be successful in treatment. He did not consider that under existing circumstances any useful purpose would be served by scheduling tuberculosis as one of the notifiable infectious diseases, but there were no doubt cases in which the medical officer of health might with advantage supplement the advice and action of the medical adviser, and it was desirable that in every case thorough disinfection of the house, &c., should take place. The remarkable decline in the mortality from tuberculous disease in Liverpool was in the main owing to sanitary measures having as one principal object improvements in ventilation. These improvements, carefully thought out and slowly elaborated, had reduced the mortality per 100,000 from all forms of tuberculosis from 430 in 1866 to 292 in 1896, the rate above five years of age from phthisis having fallen from 363 to 233, and below five years of age from tabes mesenterica, &c., from 637 to 497 in the period alluded to. He remarked on the analogy furnished by tuberculosis in cows, those shippons which were ill-ventilated and insanitary being centres of infection, whilst in the well-ventilated ones the disease was rare. 4 per cent. of the samples of milk taken from shippons in Liverpool were found to be tuberculous, but in samples of country milk more than three times that amount was found—viz., 13 per cent. This instances the much greater advance made in cities than in rural districts in these matters. —Dr. BUCHANAN considered it necessary in the treatment of tubercle to remove the patient to an atmosphere from which the tubercle bacillus and other organisms were absent, and, if possible, to one in which they cannot live and at the same time to increase the resistance of the host. He advocated sanatoria for collective cases but urged that we must all strive to make a man's dwelling his sanatorium. Fifty years ago Professor Virchow said "it is the duty of mankind to overcome tuberculosis as scurvy has been overcome."—Dr. CATON, who had visited various foreign sanatoria, expressed regret that hitherto Great Britain should have lagged behind continental nations in this matter. In proximity to every great centre of population sanatoria ought to be established by municipalities, county councils, or boards of guardians. The expenditure involved would in the end prove an economy as well as delivering the population from the scourge of tuberculosis. General hospitals ought not to admit cases of phthisis. Dr. Caton urged the desirability of making widely known the infectivity of phthisis.—Dr. A. DAVIDSON pointed out that the principle of open-air treatment of phthisis was not new and quoted from Dr. Hughes Bennett's book, published in 1853, where it was considered of supreme importance and where he deprecated the sending of phthisical patients to warm climates abroad. Dr. Bennett expressed a hope that large sanatoria would be established in this country. Dr. Davidson referred to the great success which, in his experience, attended the plan of sending young phthisical patients to winter on the north cost of Wales.—Dr. GRÜNBAUM thought that, desirable as sanatoria might be, too much must not be expected and promised as regards results. The infectivity of phthisis was of a different order to that of typhus fever, small-pox, &c., as was probably also the morbific agent. The evidence showed that hygienic measures had not the same remarkable effects on tubercle, typhoid fever, and diphtheria as on scarlet fever, small-pox, and typhus fever.—Dr. T. R. BRADSHAW hoped the discussion would lead to some practical steps being taken in Liverpool. He thought a good deal was to be said for notification; it need not of necessity prevent

Digitized by Google

a phthisical patient from following his employment, as each case could be treated on its merits. He mentioned instances where permitting phthisical patients to follow their occupations indiscriminately as at present was not without danger to other persons. He thought the Medical Institution ought to endeavour to move the public in the matter.—Dr. ABRAM gave two instances to illustrate the marked infectivity of pulmonary tuberculosis. He drew attention to what, in his opinion, was generally overlooked—namely, that the reputation of the open-air treatment was in the main based on the results obtained in high-altitude sanatoria. He counselled moderation in urging the virtues of low-lying sanatoria lest there should come a reaction in the public mind with regard to the provision of pure air for tuberculous patients.—Dr. CARTER, Dr. BARR, Dr. GLYNN, Dr. MACALISTER, Mr. S. KELLETT SMITH, and Dr. STOOKES took part in the discussion.

CLINICAL SOCIETY OF MANCHESTER.

Exhibition of Cases.—Extra-uterine Pregnancy.—Placenta Prævia.

A MEETING of this society was held on Nov. 15th, Dr. A. HILL GRIFFITH, President, being in the chair.

Dr. JUDSON BURY showed the following cases of Nervous Disease:—(1) Hemiplegia from Embolism the result of Aortic Disease; (2) Hemiplegia the result of Syphilitic Endarteritis; (3) Syringomyelia; and (4) Chronic Anterior Poliomyelitis affecting a Limb already Atrophied in consequence of Infantile Paralysis in Early Life.

Dr. WAHLTUCH showed two cases. The first was that of a man, aged forty-two years, who had come under his care at the Hulme Dispensary on Oct. 27th, 1898, suffering from Paralysis of the Median Nerve. He had been ill since May 23rd, when he awoke with pain in the neck and along the left arm, the forearm, and the palm of the hand. There was numbness in the second and third, and, to some extent, in the fourth, fingers. Treatment by massage and electricity twice a week had been carried out during the preceding three weeks. The patient had felt better after each application; the pains were less frequent and less severe and the numbness was almost gone. The second case was one of Paralysis of the Deltoid of the Left Arm. The patient, a man, aged sixty-four years, had had a fall in August last, and a fortnight later had felt weakness and pain in the left arm, especially in the deltoid. The muscle was wasted and the patient could not lift up his arm. He had attended as an out-patient at the Hulme Dispensary on Oct. 1st. Treatment by massage and electricity had been carried out. Slight improvement had taken place at the end of four weeks.

Dr. DULBERG showed a case of Subacute Articular Rheumatism in a patient who was undergoing the Tallerman treatment. He had benefited considerably, although he had had only three baths. The treatment was described and the opinion was expressed that it deserved to be tried in suitable cases.

Dr. T. ARTHUR HELME read notes of a case of Extra-uterine Pregnancy of Twelve Years' Duration. The history pointed to the facts that the extra-uterine pregnancy had existed for twelve years; that ten years ago the patient had given birth to a child *per vias naturales*, whilst the ectopic pregnancy was still there; and that the latter had lain dormant until two years ago, when suppuration began and pus was discharged *per vaginam*. Dr. Helme opened through the posterior vaginal fornix, removing the fœtal skeleton and draining the sac through the vagina.

Dr. HELME also discussed the Treatment of Placenta Prævia, dealing especially with the central variety and showing the correctness on anatomical grounds of Barnes's description of his method of "stripping the placenta" from that portion of the uterus below Barnes's boundary line, now known as Bandl's ring—the contraction or retraction ring.

EDINBURGH OBSTETRICAL SOCIETY.

Presidential Address: Surgical Interference in Gynæcology.—Latency of Gonorrhœal Infection.

A MEETING of this society was held on Nov. 9th, Dr. HALLIDAY CROOM, President, being in the chair.

The following office-bearers were elected for the ensuing session:—President: Dr. J. Halliday Croom. Vice-Presidents: Dr. N. T. Brewis and Dr. J. W. Ballantyne. Treasurer: Dr. W. Craig. Secretaries: Dr. J. Haig Ferguson and Dr. W. Fordyce. Librarian: Dr. R. Milne Murray. Editor of Transactions: Dr. J. W. Ballantyne. Members of Council: Professor Simpson, Dr. Alex. Ballantyne, Dr. Melville Dunlop, Dr. F. W. N. Haultain, Dr. Owen Mackness, Dr. Macvie, Dr. Berry Hart, and Dr. T. Brown Darling.

Dr. CROOM read his presidential address on Surgical Interference in Gynæcology. It was with satisfaction at the commencement of the sixtieth session that the society could look back upon the work accomplished in former years. Originated by the exceptional brilliance of Sir James Y. Simpson, it did much to further gynæcology in Scotland, and there was probably no society in Scotland which had met month by month and lived and flourished as this had done. During the last ten years it had preserved its obstetrical character, as there had been twice as many papers on this branch as on the gynæcological. In recent years gynæcology had progressed into a science and might now be said to be divorced altogether from obstetrics, for by easy gradations it had digressed from the domain of the physician to that of the surgeon. The obstetric physician must be relegated to the lying-in hospital, while the gynæcologist must be classed among the surgeons of a great hospital. It must ever be a difficulty to a surgeon who is not accustomed to either obstetrical or gynæcological work to make his diagnosis a certainty. There was no doubt that the surgical treatment of diseases of women had been much overdone, as in the case of removal of the ovaries and tubes for inflammatory diseases. We could not be too glad that the tendency now was becoming more and more conservative and that the perfected methods of antiseptic surgery enabled us to deal with even limited areas of affection in ovaries and tubes. We realise that it is only in grave pathological lesions that these organs should be entirely removed. The means of dealing with a tubal pregnancy before rupture were well determined and its removal was a matter of comparative safety compared with the risks of rupture. But it was just possible that the resort to the knife had been overdone and that many early ectopic gestations, even after rupture, had become absorbed and disappeared without the arbitrament of the knife. The operation for the entire removal of the uterus by the vagina had developed enormously. It could be done swiftly and easily in a few minutes, but the question was in the case of carcinoma if it tended to the prolongation of the life of the patient. It stopped hæmorrhage and fœtid discharge, but relief was only temporary. Even temporary alleviation would be an advantage were it not that with the recurrence of the disease the ultimate pain and suffering were greater than if there had been no interference at all. In an experience of twenty years Dr. Croom had tabulated every case of malignant disease of the uterus which had come under his supervision. They amounted to 260, and of these only 15 fulfilled all the conditions requisite to justify hysterectomy with expectation of success. Of these 12 were operated on, and though the patients—to use the hackneyed phrase—made absolutely uneventful recoveries they all died within a year and, in Dr. Croom's opinion, with greater suffering than if they had been left alone. This applied to several cases in which the disease was absolutely confined to the fundus and where, as far as could be made out, there was no involvement of the broad ligament; and yet in all the disease recurred in the peritoneum and the patient died in great distress within the year. After an initial diagnosis of cancer a woman's expectation of life was from two to two and a half years. Many forms of cancer were painless and most destroyed life by hæmorrhage, exhaustion, and uræmic poisoning. The question was: Did women live longer lives and die less painful deaths if the uterus were removed or if the disease were allowed to run its ordinary course? In Dr. Croom's opinion surgical interference was better left alone. Statistics might be given of the German results, but whatever the explanation might be neither in this country nor in America could results be obtained at all in comparison with what the Germans claim. Cancer in Germany must be one thing and cancer in Great Britain another, or the respective diagnostic skill of the two countries must vary considerably, or women must present themselves to German surgeons at a period when the disease was in its most initial stage, when it was confined to a small nodule in the cervix or limited to the mucous membrane of the cervix. Another explanation of the discrepancy might be that cases of marked cervical catarrh and gross erosion.

Digitized by Google

had been mistaken for cervical cancer and treated as such. This had occurred in the personal knowledge of Dr. Croom. And it was easy to mistake advanced senile uterine catarrh of a pronounced type for a fundal cancer. In all Dr. Croom's cases before operation the suspected tissue was examined microscopically. The whole point was that it was quite conceivable that with a cancer very early diagnosed and operated on the prolongation of life was possible, but after a cancer had developed beyond its most initial stage Dr. Croom held that the removal of the uterus did not prolong life and that the subsequent death was infinitely more terrible. As regarded the operation perhaps Edward Kelly, acting on Freund's suggestion, might be on the right lines in giving up vaginal hysterectomy for cancer and dealing with the whole uterus and broad ligaments from above. The operation of vaginal hysterectomy had been so improved that anything less than a successful immediate issue would be scarcely warranted, but that "the patient left the hospital well" was no addition to our knowledge of results. Cancer was extraordinarily prevalent, but in our efforts to ameliorate it we seemed to have come against a dead wall. It was possible that the solution of the question might yet be found in treatment in some animal extract or in the principle of antitoxin remedies. In groping for light it was our duty to keep an open mind for any theory and to welcome any suggestion, however extreme, in dealing with this awful disease. At the present day every surgical proceeding was accepted and adopted; it was striking to think how medical innovations were received with distrust. Even anæsthesia was at first scorned and regarded in the light of charlatanism. With regard to hysterectomy for conditions other than cancer, such as prolapsus, subinvolution, and inflammatory disease of the uterus and appendages, the operation was one which from its simplicity required to be safeguarded. It bade fair to be overdone. Unlike uterine cancer, these diseases were not in themselves necessarily fatal and the symptoms and discomfort to which they gave rise could in many cases be alleviated by other less drastic measures. In small bleeding fibroids and prolonged hæmorrhages from the uterus which had resisted all other means of treatment this operation gave, perhaps, the best prospect of cure. With regard to fibroids, removal of the ovaries for bleeding or rapidly growing tumours was gradually being supplanted by the operation of abdominal hysterectomy, an operation much more certain in its results though more dangerous for the moment. Even yet the death-rate was high and it was an operation which, except in the hands of experienced operators, was not to be undertaken without considerable anxiety.

Dr. MILNE MURRAY read notes on a case bearing on the Latency of Gonorrhœal Infection. He had attended a woman in three confinements; the mother did well each time. The first two children were healthy and remained so. The third child showed signs of ophthalmia on the third day after labour and soon developed very severe symptoms. The right eye was affected some days after the left. The mother had not suffered from any leucorrhœa before the birth of the child and the father was at that time free from any symptoms. He had contracted gonorrhœa eight years before and to all appearance was soon quite cured. No other possible source of the ophthalmia could be found but latency in the father. Dr. Milne Murray discussed the question and adduced Noeggerath and Tait as giving cases where there was latency for as long a period.—Professor SIMPSON, Dr. CROOM, Dr. HAULTAIN, and others joined in the discussion.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—A meeting of this society was held in the library of the Royal Infirmary, Newcastle-on-Tyne, on Nov. 10th, Dr. Limont, President, being in the chair.—Dr. R. A. Bolam gave a valuable and interesting Demonstration on the Nutrient Value of various Meat Extracts, &c.—Dr. T. Beattie, in the absence of Dr. Drummond, showed: 1. A child, aged nine years, suffering from Congenital Heart in whom the cyanosis and the clubbing of fingers and toes were extreme. The murmurs present indicated pulmonary stenosis, tricuspid regurgitation, and patent foramen ovale. 2. A child, aged fifteen years, with Congenital Heart in which patent ductus arteriosus had been diagnosed. Over a limited area in the pulmonary region there were a continuous thrill and a continuous buzzing murmur having systolic and diastolic exacerbations simulating the murmur of an arterio-venous aneurysm. 3. A man with Aneurysm of the Ascending Aortic Arch which had apparently ruptured into the superior vena cava, evidenced by sudden swelling of the head, neck, arms, and upper part of the thorax, intense cyanosis, marked pulsation of the veins of the neck, continuous thrill, and a buzzing murmur heard with maximum intensity over the first and second right interspaces close to the sternum. 4. A man with Aneurysm Springing from the Left Side of the Arch and presenting above the left clavicle, and therefore simulating a subclavian aneurysm. The intra-thoracic origin was proved by definite signs of pressure on the left bronchus. 5. A case illustrating the diagnosis of Adherent Pericardium.—Dr. Beattie, for Dr. Oliver, brought forward a man showing a Pulsating Tumour in the Back presenting opposite the fourth and fifth ribs to the left of the spine. The ribs were eroded and although no bruit was audible the tumour was thought to be an aneurysm of the descending aorta.—Dr. Hume showed a young miner in whom he had Resected a Foot of Small Intestine which had been torn from its mesentery as the result of a bicycle accident, the subsequent enterorrhaphy being effected by a Murphy's button.—Dr. Hume and Dr. H. Bramwell showed an old man after operation for Cerebral Abscess following a head injury. Previously to the operation the patient had been completely hemiplegic and after evacuation of pus from the hemisphere rapidly and completely recovered.—Mr. Albert Martin brought forward the following cases: 1. A boy, aged nine years, with Bilateral Congenital Displacement of the Hip-joint, comparing the gait with that of a case of pseudo-hypertrophic paralysis. 2. An infant with Congenital Radial Deflection of the Terminal Phalanges of both Thumbs, one of which had been cured by division of resisting structures. 3. An infant with congenital suppression of the Growth of the Forearm and the Hand with Webbing of the Fingers.—Mr. Rutherford Morison showed: 1. A man after Pylorectomy for Glandular Carcinoma, who had made an uninterrupted recovery and is now able to take ordinary food. 2. Another patient who, after Pylorectomy for Glandular Carcinoma, is now able to eat anything and has passed a stone since operation. 3. A patient after Removal of the Pyloric Half of the Stomach, with specimen. Mr. Morison described by means of diagrams the method of operation and stated that now, one month after the operation, the patient was able to eat ordinary diet.—Dr. Limont showed the following interesting examples of skin disease: (1) A case of Lichen; (2) a case of Seborrhœic Dermatitis; (3) cases of Rodent Ulcer; (4) a case of Pityriasis Rubra; and (5) a case of Pustular Syphilide.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 16th, Mr. T. D. Pryce, President, being in the chair.—A paper was read by Dr. W. B. Ransom on the Vis Medicatrix Naturæ. The paper pointed out the large range of conditions under which living beings could maintain health and the great adaptability of animals and plants to variations in these conditions. Repair of injury and regeneration of lost parts were shown to be extensive in the highest, as in the lowest, forms of life and the fact of a functional reserve of energy was insisted on. The indirect influence of parts of the organism on the whole was illustrated, and, finally, the means by which the body resists the attacks of microbes were put forward.—The paper was discussed by the President and Dr. Cattle.—Mr. R. C. Chicken showed Three Stones which had been removed from a Female Urinary Bladder by Dilatation of the Urethra. There were two smaller ones lying free in the bladder itself and one large one which was contained in a sacculus. The latter measured 2¼ in. by 1⅝ in. in diameter and 6½ in. by 4⅝ in. in circumference, and it weighed 795 grains. Mr. Chicken observed that in all probability the smaller stones were fragments broken off from the original one and had since grown by accretion. As far as he could ascertain, Mr. Chicken said, the large stone was the largest which had ever been removed by dilatation of the urethra and was much larger than the limit of size laid down by authorities as being sufficiently large for this method of removal to be adopted without injury. Inasmuch as there were no injurious after-effects following the operation in his case Mr. Chicken gave it as his opinion that removal by this method ought to be adopted in every case of stone in the female bladder where the size did not exceed the dimensions of the one he had removed. — Mr. Anderson showed: 1. Uterus removed by the Abdominal Method for Fibroid

Digitized by Google

Tumours. The patient's age was forty-eight years; the tumour had been noticed for three years. The menopause began two years before operation. There had been no hæmorrhage other than the ordinary catamenial discharge. The tumour had been rapidly growing since it was noticed. The whole tumour weighed 11¼ lb. and reached nearly to the liver, occupying the right loin. In parts it was calcified. 2. Two Stones removed from the Pelvis of a Kidney. Symptoms of stone had existed for twenty years, but during the whole of this time there had been no hæmaturia observed. 3. Appendix Vermiformis containing a Fæcal Concretion removed at a period of quiescence; there had been three attacks of appendicitis and there was no perforation.

BRITISH ORTHOPÆDIC SOCIETY.—A meeting of this society was held on Oct. 21st at the National Orthopædic Hospital, Great Portland-street, Mr. A. H. Tubby being in the chair.—Mr. Luke Freer showed a Modification of Holland's Arch for Flat-foot containing a pad of porous rubber in place of steel which he had found much more satisfactory.—Mr. Muirhead Little, Mr. Openshaw, and Mr. Tubby showed some interesting cases of Tendon Transplantation. In Mr. Little's cases the peroneus was inserted into the tendo Achillis. In one of these the wound suppurated freely, in spite of which there had been some improvement; another operated on in a similar manner had so far been most successful. He thought the kangaroo tendon had been responsible for the suppuration. In Mr. Openshaw's cases one had been treated by exposing and dividing the peroneus longus and tibialis posticus; then passing the forceps through an incision in front of the tendo Achillis he drew the peroneus longus across the back of the leg and stitched it to the tibialis posticus with the idea of correcting the valgus by diminishing the power of the peroneus and increasing the power of the tibialis posticus. The result had been fairly good.—Mr. Tubby showed a case of Congenital Hip Displacement treated by the Open Method. Mr. Robert Jones and he had attended the case together at the Evelina Hospital. The girl was twelve years old and had 2½ in. shortening. They made an anterior incision. There was a rough bony prominence inside the acetabulum. They made a square surface on the head of the femur, cut two-thirds through the neck of the femur, and gave it a twist to correct the inversion. Their object was not so much to make an acetabulum as to bring about fibrous union. By this method uprising was prevented, but there remained some shortening as the neck of the femur was horizontal. The case had been previously treated by Lorenz's operation. — In the subsequent discussion Mr. Reeves said that he had always opposed these operations. A case of his own which was sent to Vienna to be operated upon was not one bit benefited.—Mr. Openshaw said that he had performed six operations of the kind, but he considered that only two of them were really successful.—The discussion was continued by Mr. Eve, Mr. Noble Smith, Mr. Muirhead Little, and Mr. Keetley, and a number of skiagrams illustrative of this condition were shown.

FORFARSHIRE MEDICAL ASSOCIATION.—This society met in the University College, Dundee, on Nov. 2nd, Dr. J. Mackie Whyte, vice-president, being in the chair.—Mr. Greig showed (1) a Cast of the Head of a Microcephalic Idiot whose age at death was twenty-one years, the measurement from glabella to inion being 12 in., and (2) a Cathcartine Cast of a Hypertrophied Prepuce.—Dr. Rogers read a paper on Œdema Neonatorum, describing the case of a child who was born at the eighth month and who developed symptoms of this disease on the third day. On the eighteenth day acute enteritis set in and after recovery from this the œdema disappeared and the child is now well and putting on flesh. He believed that in this case the condition was due to atelectasis and a patent foramen ovale. He then discussed the points which distinguished it from sclerema.—Dr. Buist did not think that Dr. Rogers's case could be distinguished from one of sclerema. — Dr. Kynoch considered that œdema and sclerema were the early and later stages of the same disease.—Dr. McVicar read notes of a case of Gastrostomy which he had performed for cancer of the cardiac end of the stomach. The patient was a woman, aged fifty-three years. Up to the third day after the operation there was sickness and retching and later there was some trouble owing to leakage, otherwise the patient had done well till three months after the operation, when pain immediately on receiving food again troubled her. This, Dr. McVicar thought, was due to extension of the disease.—Dr. Buist read a paper on the Treatment of Ineradicable Cancer of the Uterus by Interference with the Blood-supply, giving an account of a case in which he had ligatured the uterine arteries and removed the ovaries. This treatment caused a diminution in the discharge, but apparently very little alteration in the rate of growth of the disease. He showed the bladder, uterus, and rectum, which were all involved to some extent in the growth.

ÆSCULAPIAN SOCIETY OF LONDON.—A meeting of this society was held on Nov. 18th, the President, Mr. D. H. Goodsall, being in the chair.—Dr. A. Haig read a paper on Diabetes and showed a man, aged thirty years, a diabetic subject, who had gained 5 kilos. in six months under treatment by salicylate, avoidance of meat, and the giving of "Protene" biscuits. Dr. Haig said that there was always an excess of uric acid in the blood, that all the useful drugs in diabetes relieve the circulation of uric acid, that diabetic coma was due to uric acid and was not a part of diabetes, and that all was a result of defective combustion due to a defective capillary circulation. Glucose present was made up partly of a functional remediable and partly of an organic irremediable factor.—Dr. Arthur T. Davies showed two specimens of Œsophageal Carcinoma from men aged respectively fifty and fifty-two years. In one the lower part of the gullet and the outer coat of the aorta were involved and the right lung was tuberculous, as determined microscopically; in the other ulceration extended from the œsophagus through the pleura into the lung. In the case of the latter patient there was a history of difficulty in swallowing for a period of four months.—Mr. W. L. Brown showed a Rectal Slough from a child with rectal prolapse which came away on the tip of the examining finger as a complete ring about 2 cm. in length. There had been bloody stools for six months and there was a tight phimosis.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The second meeting of the session was held in the Medical Library of University College on Nov. 9th, Dr. R. Roxburgh being in the chair.—Mr. Carwardine showed a patient and specimens of Hydatid of the Liver.—Dr. Stack (for Dr. J. E. Shaw) showed some interesting specimens of Brain Tumour.—Dr. Michell Clarke and Mr. Roger Williams spoke on the subject. — Mr. Carwardine showed a specimen of Double Hydro-salpinx.—Mr. Paul Bush showed a portion of a Large Tumour which he had successfully removed from the axilla, which he considered to be tuberculous.—Mr. Morton, Mr. Lace, and Mr. R. Williams commented on the tumour.—Mr. Paul Bush showed a series of cases of Enlarged Bursæ in housemaid's knee.—Mr. Harsant, Mr. Barclay, and Dr. Roxburgh spoke on the subject.—Dr. B. Rogers showed some microscopic specimens of Blood from a case of Leucocythæmia.—Dr. Stack showed a specimen of Aneurysm of the Vena Cava; Professor Fawcett remarked on the specimen.—Dr. H. L. Ormerod read a most instructive paper on a case of Ulcerative Endocarditis.—Dr. Shingleton Smith, Dr. Waldo, Dr. B. Rogers, Dr. Parker, Dr. Symes, Dr. W. C. Swayne, Mr. R. Williams and Dr. F. H. Edgeworth discussed the paper.

MANCHESTER THERAPEUTICAL SOCIETY. — A meeting of this society was held at the Owens College on Nov. 1st, Dr. Leech, the President, being in the chair.—Dr. R. B. Wild read a communication on the Toxic Effects of Boric Acid in which he narrated two cases in which dermatitis and other disagreeable symptoms were produced by the continued administration of boric acid in doses of from 10 to 15 gr. Dr. Wild also related experiments which he had made in order to test the rate of elimination of boric acid by the urine. He found that it was excreted partly as free boric acid and partly as borax. He believed that with diseased kidneys elimination might be very slow and thus favour the onset of toxic symptoms. He thought it was not justifiable to add boric acid to foods in such large quantities as was done sometimes.—A discussion then took place on the Various Forms of Extract of Meat and Similar Preparations, a large number of samples being shown. The general opinion seemed to be that though some of these were readily taken and might serve occasionally as useful stimulants the majority were almost devoid of nutritive properties and that probably the raw meat juice

Digitized by Google

freshly prepared was more useful than the proprietary preparations.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Nov. 15th, Mr. J. Foster Palmer, President, being in the chair.—Dr. J. B. Ball read a paper on the Indications for Operation in Cases of Adenoid Vegetations of the Naso-pharynx. He recapitulated the main symptoms of the disease, laying stress on those which he considered to furnish indications for operative interference. He strongly disagreed with those who advise operation in every case of adenoids regardless of whether symptoms are present or not, and deprecated the tendency which existed in many quarters to exaggerate the ill effects of these growths. At the same time he insisted on the importance of early operation in cases where operation was indicated. He finally enumerated the symptoms which he believed to indicate an operation. The President, Dr. C. C. Gibbes, Dr. C. A. Morris, Dr. V. Dickinson, Dr. P. White and Dr. D. Vinrace also spoke and Dr. Ball replied.

HULL MEDICAL SOCIETY.—The following have been elected as office-bearers for the session 1898–99:—President: Dr. Alfred Parkin. Vice-Presidents: Dr. Edward O. Daly and Mr. A. Legge Roe. Librarian: Dr. James McNidder. Council: Dr. T. Cameron, Mr. A. G. Francis, Dr. R. Grieve, Dr. E. M. Hainworth, Mr. E. H. Howlett, Dr. David Lowson, Dr. John Merson, and Mr. H. W. Pigeon. Honorary Secretary: Dr. James L. Waters.

NEWPORT MEDICAL SOCIETY.—A meeting of this Society was held on Nov. 2nd, the President, Mr. H. E. Williams, being in the chair. Dr. Paterson (Cardiff) read an interesting paper on the Supra-tonsillar Fossa as a Starting-point of Infection (with lantern slides).—Mr. J. McGinn read notes upon and exhibited a remarkable case of Chronic Hydrocephalus.—Dr. A. G. Thomas showed a case of Double Ankylosis of the Shoulder-joint.

Reviews and Notices of Books.

Atlas of External Diseases of the Eye. By A. MAITLAND RAMSAY, M.D. Glasg., Ophthalmic Surgeon, Glasgow Royal Infirmary; Professor of Ophthalmology, St. Mungo's College, Glasgow; and Lecturer on Eye Diseases, Queen Margaret College, University of Glasgow. With 30 full-page Coloured Plates and 18 full-page Photogravures. Glasgow: James Maclehose and Sons. 1898. Quarto. Price £3 3*s.* net.

THE handsomely illustrated work which has been brought to a happy conclusion by Dr. Ramsay is one of a small class. The great expense involved in its preparation, the delicacy of the artistic work, and the comparatively limited number of purchasers combine to make both author and publisher hesitate before commencing a work of this magnitude. The chief treatises with which it can be compared are those of A. P. Demours ("Traité des Maladies des Yeux," with an atlas of 65 plates, Paris, 1818); of von Ammon, whose well-known and frequently referred to "Klinische Darstellung der Krankheiten des Menschlichen Auges," was published in Berlin in 1847, with 55 plates and 956 figures; the "Iconographie Ophtalmologique" of J. Sichel, with 80 plates, published in Paris between the years 1852–1859; and the "Pathology of the Human Eye," by John Dalrymple, published in London in 1852. All of these works were excellent in their day, Dalrymple's easily taking the lead in the brilliancy of the delineations of the diseases depicted. The original water-colour drawings of his atlas were made by Mr. Kearney and Mr. Leonard from cases occurring in the practice of Mr. Scott and Mr. Dalrymple, and in transferring the outlines to the plates Mr. Dalrymple had the good fortune to obtain the services of an accomplished artist, Mr. W. Bagge, by whose hand the illustrations were coloured. Sichel's "Iconographie" comes next and includes a number of very good chromolithographs touched up by hand. Von Ammon's drawings show less refinement than either of the others, but are yet very generally recognisable and make up for their defects by their number and variety, whilst Demours's drawings are not to be despised. All these works are—or rather were, for they are now out of print—very expensive.

The Atlas of Dr. Ramsay, at a very moderate cost, contrasts favourably with those of Demours, von Ammon, and Sichel, and in many of the drawings quite equals Dalrymple's in artistic delicacy and finish, whilst it has the great advantage of giving in numerous instances photographs of not the disease alone but the whole face of the patient, so that the expression, which is so marked a feature and so characteristic of many ophthalmic diseases, is placed before the reader in a very instructive fashion.

The value of such a work as this depends not only on the fidelity with which nature is copied, but upon the selection of typical cases, and in this respect Dr. Ramsay has exercised a wise discretion, many of the illustrations being excellent examples of the particular disease exhibited; those, for example, of eczema, of nævus of the lid, of rodent ulcer of the lid, of buphthalmos, orbital abscess, tumour of the sphenoid, aneurysm of the orbit, exophthalmic goitre, and proptosis are all good and instructive, and they are all reproductions of photographs. Some, of course, are better than others, and we certainly should not have wasted a full-page plate on a case of lagophthalmos, which, after all, only looks like a boy endeavouring with much effort to wink. The plate showing congenital ptosis with epicanthus is good and saves a world of description. The plates representing epithelioma and chancre might have been selected from better examples, and it would require a very sharp observer to distinguish from the plates the case of muco-purulent conjunctivitis from that of ophthalmia neonatorum; the former might have been omitted to make room for something else. In the smaller drawings representing the eyes alone we miss an example of keratitis punctata, which is capitally represented in Demours's twenty-seventh plate; but the drawings of gumma of the conjunctiva and of lupus of the lid, and those representing lacrymal abscess, pannus scrofulosus, xerophthalmia, pterygium, and various forms of iritis and choroiditis are very accurately pourtrayed. Dr. Ramsay has adopted a clever mode of designating the several diseases, obviating the spoiling of the plates by letterpress, which consists in prefixing to each plate a leaf of tissue paper bearing the name of the disease beneath the level of the drawing which can be seen through it. Each drawing or set of drawings representing a particular disease is accompanied by a short chapter giving the etymology, the synonyms in the English, French, German, and Italian languages, an account of the symptoms and pathology, with in many cases a brief history of the patient from whom the illustration was taken. We would particularly refer in this respect to the chapters on Glaucoma and Exophthalmic Goitre. We congratulate Dr. Ramsay on the completion of his work and regard it as a valuable contribution to British ophthalmological literature. It will prove very useful to al those who are placed at a distance from the larger centres where the advice and assistance of an ophthalmic surgeon can be obtained, and in conjunction with one or other of the treatises which we have recently had occasion to notice will enable all the ordinary and some of the extraordinary forms of the diseases of the eye to be recognised and treated with success by those who have had but little opportunity of studying them.

Gout, its Pathology and Treatment. By A. P. LUFF, M.D., F.R.C.P. Lond. London: Cassell and Co. 1898. Crown 8vo. Pp. 248. Price 5*s.*

THE author of this compact treatise has already done much work in relation to the pathology and causation of gout and we are glad that he has collected his

Digitized by Google

conclusions and presented the medical world with their practical bearings on the treatment of this common disease. His views are, as is well known, diametrically opposed to those of that energetic writer on uric acid and gout—Dr. Haig—and the reader in want of intellectual exercise will find plenty of occupation in comparing the rival theories of these two authors. The present work is divided into four parts; the first, on the pathology of gout, is mainly a reproduction of Dr. Luff's Goulstonian Lectures on the Chemistry and Pathology of Gout delivered before the Royal College of Physicians of London in 1897. In it he states his reasons for the belief that gout is of renal origin and that lesions of the kidney are an important factor in the production of ostensible gout. The chemistry of gout is fully discussed and Dr. Haig's views come in for a considerable amount of rigid criticism. In the second part, after the etiological factors have been referred to, a brief account of the clinical features of the various forms of gout is given. This portion is extremely condensed and in no way on the same lines as the rest of the work; but, as shown in the title, the clinical aspect of the disease is outside the scope of the present essay. The third part consists of the author's experimental researches into certain points bearing on the treatment of gout. He finds that there is no reason to believe that an acid dyscrasia underlies the gouty condition and that the noxious properties of some wines and beer are not accounted for by the contained acids, ethers, or sugar; he considers that these drinks lead to gout by exercising such an effect on the liver that more glycocine is produced; this body is then converted by the kidneys into uric acid; and if the kidneys are not capable of excretion the uric acid thus formed accumulates in the body. Another important point is that the mineral ash of most vegetables increases the solubility of sodium biurate, while the mineral ash of meat has the opposite result. It further appears that the treatment of gout by alkalies, lithium, piperazine, and salicylates is erroneous. After these original and certainly somewhat startling conclusions the practical treatment is considered in the fourth and concluding section.

Colchicum is recommended and is probably useful in that it diminishes the production of uric acid; it may be given every other night in the form of a pill composed of 1 gr. each of the acetic extract of colchicum and of blue pill and of 2 gr. of euonymin. A mixture of 30 gr. of chloride of ammonium and 15 minims of dilute nitro-hydrochloric acid is also advisable. Full attention is also given to dietetic, spa, and other forms of treatment. The style is clear and concise and the work will, doubtless, appeal to, and be appreciated by, all interested in the numerous problems surrounding the causation and successful treatment of gout.

Uric Acid as a Factor in the Causation of Disease. By ALEXANDER HAIG, M.A., M.D. Oxon., F.R.C.P. Lond. Fourth edition. London: J. & A. Churchill. 1897. Pp. xiii.–698. Price 12*s.* 6*d.*

IT may be conceded that Dr. Haig has done good service in insisting upon the uric acid factor in the causation of certain diseases—notably migraine. Starting from observations on his own case he has shown how migraine can be held in check and reasonably treated. It is the experience of those who have adopted his line of treatment that at least in many cases it is successful. It is probable that uric acid plays a part in the causation of certain other diseases besides migraine and, of course, gout in its various manifestations, though the evidence of this is by no means so decisive. It is, however, very easy to push the uric acid theory of disease to unwarranted excess, and this, in our judgment, Dr. Haig has done. In this fourth edition of his book he has endeavoured to include so many and such various diseases within the uric acid fold that it is difficult to take him seriously. When we proceed to inquire into the solid basis of exact fact upon which many of his propositions rest we find that it is not always so solid or so exact as we have a right to demand. It has been pointed out again and again that Haycraft's method for estimating uric acid, upon which all Dr. Haig's statements and figures are based, is by no means of sufficient accuracy. We have before protested in these columns against the use of the barbarous word "uricacidæmia." We now find the term "collæmia" used as a synonym of uricacidæmia on the assumption that the rise of blood-pressure met with in certain uric acid diseases is due to mechanical capillary obstruction by uric acid salts in the colloid form. No adequate grounds are set forth for the assumption. Dr. Haig is a vegetarian and he is of opinion that much uric acid is introduced into the body as such in certain articles of food, especially meats and their derivatives. The processes by which the estimations have been made are not such as to satisfy an organic chemist. Space fails us even to enumerate all the diseases which the author connects in one way or another with uric acid, much less to criticise his various lines of reasoning. There appears to us to be a considerable amount of assumption and in many cases a somewhat slender basis of indisputable fact. It is indeed to be regretted that by pushing his theories to extremes Dr. Haig tends to discredit the real importance of many of his earlier observations.

Laboratoire Bactériologique de l'Hôpital Grec d'Alexandrie: Recherches Bactériologiques sur la Pathogénie de la Dysenterie et de l'Abcès du Foie d'Égypte. Faites par le Docteur A. P. PETRIDIS, Médecin adjoint au service du Docteur Zancarol et Directeur du Laboratoire Bactériologique. (*Bacteriological Laboratory of the Greek Hospital, Alexandria: Bacteriological Researches on the Pathogeny of the Dysentery and the Abscess of the Liver of Egypt.* By Dr. A. P. PETRIDIS, Assistant Medical Officer to Dr. Zancarol and Director of the Bacteriological Laboratory.) Alexandrie. 1898.

As a result of observations on 9 cases of multiple abscess of the liver in the human subject which were opened, but which were followed by death, on 15 similar cases which recovered and of which a bacteriological examination was made during life, and on 11 other cases in which no bacteriological examination of the blood was made during life (6 of which recovered and 5 died), Dr. Petridis has no hesitation in coming to the conclusion that the endemic dysentery of Egypt is microbic in its origin and that the real cause is not amœbic but streptococcic in character. He finds that by injecting the streptococci separated from these cases directly into the rectum of a cat that he is able to produce in about half of the cases so treated a condition similar in character to dysentery. As bearing out his contention he also gives the following observations: the pus from one of these abscesses in the human subject, taken at the time of operation, almost invariably contains streptococci which may be isolated on cultivation. Sections of the hepatic tissue taken during the operation or after death also contain streptococci or cocci in zooglœa. Blood drawn before the operation always contained streptococci. Similar observations were made in cats submitted to experiment. Abscess of the liver he believes in most cases results from dysentery or other irritation of the intestinal mucous membrane, by which exfoliation of the epithelium is brought about. Amongst the causes of such conditions he includes the entozoa. In every case where an abscess of the liver was produced experimentally in cats the dysenteric condition of the intestinal canal could be demonstrated, but in not a single abscess of the liver of the cat was he able to demonstrate the presence of numerous living amœbæ. Abscess of the liver usually commences as

Digitized by Google

minute foci of suppuration which gradually run into one another and form a single large abscess. In those cases, however, in which they are far apart these abscesses cannot run together and so may remain "multiple." These opinions, based on so many observations, cannot but carry weight in the discussion concerning the part that streptococci play in determining dysenteric abscess of the liver.

LIBRARY TABLE.

A Manual of Operative Surgery. By LEWIS A. STIMSON, B.A., M.D., Surgeon to the New York, Bellevue, and Hudson-street Hospitals; Professor of Surgery in the University of the City of New York, &c.; and JOHN ROGERS, jun., B.A., M.D., Assistant Demonstrator of Anatomy in the College of Physicians and Surgeons (Columbia College), New York; Surgeon of the Out-patient Staff, Hudson-street Hospital. Third Edition, with 334 Illustrations. London: H. K. Lewis. 1897. Pp. 598. 8vo. Price 12*s.* 6*d.* net.—The first two editions of this book were so well known and appreciated in this country that it would almost suffice to say that this, the third edition, is as good as its predecessors. Ten years have elapsed since the second edition appeared, and so many important changes have taken place in the methods of doing many operations and so many new operations have been introduced, that it was found necessary almost wholly to re-write the book in order to bring it fully up to date. For this purpose Dr. Stimson associated with himself Dr. Rogers, who has had the work of collecting the material and writing the book; but it has all been carried out under Dr. Stimson's supervision. The result is eminently satisfactory, and we find in a volume of just 600 pages all the essential parts of what might very easily have been made to occupy a much larger work. Much space has been saved by excluding from the volume all accounts of the conditions for which the operation may be required. All the common and most of the rarer operations are given and the descriptions, though brief, are sufficient to enable a surgeon to perform any operation if previously unacquainted with it. The special surgery of the eye occupies 50 pages, and gynæcological operations are described in about as many. In our opinion the best chapter in the volume is that devoted to the plastic surgery of the face; it is better than the matter which is to be found in most special treatises on the subject. The whole work is profusely illustrated and can be recommended to the student as clear, concise, and complete. The only fault which we have to find with the book is that the index is not sufficiently full.

Brief Essays on Orthopædic Surgery. By NEWTON M. SHAFFER, M.D., Surgeon-in-chief to the New York Orthopædic Dispensary and Hospital; Clinical Professor of Orthopædic Surgery, University of New York City, &c. New York: D. Appleton and Co. 1898.—This little volume consists of seven articles which have already appeared in some American medical journals at various times during the last few years and their general object is to insist upon the desirability of the existence of orthopædic surgery as a specialty. The author points out that special training in orthopædics is needed to enable a surgeon to obtain the best results in this department and that this can only be obtained at special hospitals or at general hospitals where a special orthopædic department has been established. He argues that a surgeon should give to the instrument-maker the measurements and patterns for the apparatus required in an orthopædic case and that to leave the measurement and fitting to the instrument-maker who cannot appreciate the requirements of the case is only to court failure. Every orthopædic department should have a workshop where the apparatus can be made, and Dr. Shaffer shows that this workshop may easily be made self-supporting by selling the instruments to the patients at cost price. If this be done they obtain the apparatus at a much less cost than from the ordinary instrument-maker. One further point is raised in this book: the author thinks that an orthopædic surgeon should operate only on those cases which require special treatment after the operation and that all other cases should be handed over to the general surgeon.

Where Two Worlds Meet. By ROSA E. MARCH. London: Skeffington and Son. Price 2*s.* 6*d.* net.—This is a collection of thoughtful little essays written in a simple and devotional spirit. The one entitled "Break up your Fallow Ground" was specially written for the sick and would very likely be of considerable service to those of a particular kind of temperament. There is a contemplative side of the religious life as well as an active one.

The Natural History of Digestion. By A. LOCKHART GILLESPIE, M.D., F.R.C.P.Edin. Pp. 427, figs. 48, diagrams 12, charts 23. Price 6*s.* The Contemporary Science Series. Edited by HAVELOCK ELLIS. London: Walter Scott. 1898.—This work gives an account of the processes of digestion both in plants and animals. This in itself is no slight task, but there is more than this in the volume before us, for chapters on metabolism, animal heat, stimulants, and food have been added so as to render the whole more complete. The first chapter contains an interesting *résumé* of the theories held by the ancients on digestion and records the phases which accepted opinion has since gone through, thus carrying the reader up to comparatively recent times. After an interesting description of carnivorous plants the author goes on—in Chapter IV. and those following—to the anatomy and physiology of digestion. This constitutes the bulk of the work and it is done with great ability. Considerable detail has been introduced, especially in small print, and the outcome is a useful source of reference, written in a clear and concise style and well illustrated by figures, diagrams, and charts, which will be welcomed by the medical profession as well as by the lay public for whom the Contemporary Science Series is chiefly intended.

Contributions to Clinical Medicine. By T. MCCALL ANDERSON, M.D.Glasg. Edited by JAMES HINSHELWOOD, M.A., M.D. Glasg. 8vo, cloth. Pp. 415, 28 Illustrations. Edinburgh and London: Young J. Pentland. 1898.—This is a collection of commentaries on cases and short clinical lectures, and is presented to the reader as an epitome of some of the experiences of one who has been a hospital physician and teacher for more than a quarter of a century. Dr. McCall Anderson's name is perhaps more generally known in connexion with diseases of the skin, and the present volume contains some valuable articles dealing with this branch of medicine, such as those on hæmidrosis, Addison's disease, and hydroa æstivale. The "Contributions," some of which have been already published, are arranged under six headings, general diseases coming first, then those of the nervous, the circulatory, the respiratory, the digestive, and the urinary systems. In the course of some remarks on the phenomena of embolism a remarkable case is given in which it appeared probable that a primary hydatid cyst in the heart gave rise to multiple embolism of daughter cysts in the carotids and other branches of the aorta. Another very interesting paper—especially at the present time when the subject of the treatment of tuberculosis is so much to the fore—is that on the Curability of Acute Phthisis (galloping consumption). Altogether these extracts from a physician's case-book are well worth reading and will prove especially attractive to the author's old students who may, perhaps, as he suggests, recognise some familiar friends among the recorded cases.

JOURNALS AND REVIEWS.

Journal of Experimental Medicine (New York and London: D. Appleton and Co.).—In No. 3 of the third volume the first two papers deal with a case of Teratoma of the Abdominal Cavity recorded by Dr. Douglas W. Montgomery, from a study of which Dr. Montgomery and Dr. Lewellys F. Barker are of the opinion that they have a definite fact in support of Cohnheim's vestigial doctrine regarding the origin of tumours in general. Dr. C. A. Herter contributes a Study of Fat with a special Reference to the Production of Serous Atrophy of Fat, from which he concludes that prolonged fat starvation leads to the entire disappearance of fat from the adipose tissues and that this form of fat atrophy is essentially of the same type as that found in the epicardial and perirenal fat in the human subject as the result of any wasting disease. He also notes that the lecithins of the brain and the fat of the liver are not materially reduced by fat starvation; that carbohydrate food or carbohydrate and proteid constituents of milk in considerable quantities may largely take the place of fatty food in preventing serous fat atrophy of the subcutaneous fat (fat starvation), but this may cause a very imperfect absorption of the salts of phosphoric acid from the intestine. Dr. Thomas R. Brown, in a paper on Studies on Trichinosis with Special Reference to the Increase of the Eosinophilic Cells in the Blood and Muscle, the Origin of these Cells and their Diagnostic Importance, maintains that there is a marked increase of these cells under the above-mentioned conditions; that the muscle fibres are split longitudinally and undergo a characteristic degeneration; and that near these degenerated muscle masses he has seen a few of these cells accumulated. He holds that the increase in the eosinophiles may in certain instances take place in the muscles by direct transition from the neutrophiles, as here he finds various transitional stages between the two forms. Dr. Mark Wyman Richardson draws attention to the fact that the typhoid bacillus in the urine of typhoid fever patients occurs in a proportion of about 25 per cent. in 38 cases examined in large numbers and in practically pure culture; that they occur more frequently in the later stages of the disease and especially where albuminuria is present. The importance of this observation from the point of view of preventive medicine can scarcely be over-estimated. The other papers in this number are one on the Branched Form of the Bacillus Tuberculosis in Sputum, by Dr. Charles F. Craig; another on the Effects upon the Blood of the Tufnell Method and the Calcium Salts in the Treatment of Aortic Aneurysm, by Dr. Alonzo Englebert Taylor; and Experiments on the Application of the Roentgen Rays to the Study of Anatomy, by Ernest Amory Codman, M.D. In numbers 4 and 5, Volume III., of the same journal Dr. W. T. Councilman, in an article on Acute Interstitial Nephritis, draws attention to the important part that Unna's plasma cells play in forming the cellular foci which occur in this condition during the course of diphtheria, scarlet fever, and similar conditions. These are not due necessarily to the local action of the bacteria, though in three cases plasma cells were found in the interstitial tissue in definite diseases of the kidney; but as he points out in these cases they were not found in connexion with the lesions produced directly by the bacteria but in the periphery of the purulent foci. Other papers comprise a Case of Mycetoma (Madura Foot), by James H. Wright; Pseudo-Tuberculosis Hominis Streptothricha, by Simon Flexner, M.D.; and a Comparative Study of Bovine Tubercle Bacilli and of Human Bacilli from Sputum, by Dr. Theobald Smith. This last paper is in many ways extremely suggestive; but the author does not take up any definite thesis, though he insists, and very rightly so, that from his experiments it is desirable to study the tubercle bacillus in its various aspects in order to determine the relation of the sputum bacillus to the bovine bacillus as regards virulence, and that it is especially necessary to do so in connexion with the intestinal tuberculosis met with in children. It will be gathered, however, that Dr. Smith holds to the opinion that there is a marked difference in virulence between the tubercle bacilli of cattle and those derived from sputum of the human subject. Dr. William Hallock Park and Dr. James P. Atkinson contribute a paper on the Relation of the Toxicity of Diphtheria Toxin to its Neutralising Value upon Antitoxin at Different Stages in the Growth of Culture. Whilst agreeing generally with Ehrlich as to the composition of diphtheria toxin and as to the varying neutralising value of a minimal fatal dose of toxin, they hold that epitoxoids are not necessarily formed, as suggested in Ehrlich's original paper, and that it is possible to obtain a toxin of a known and suitable neutralising value by using the same bacillus—not necessarily the same broth—but growing the culture at the same temperature for a definite period of time. They think that this will give a better standard than, or at any rate an equally good standard as, Ehrlich's standard antitoxin. Dr. T. M. Cheeseman and Dr. S. J. Meltzer, in a most interesting paper on the Inoculation of Bacteria into the Spleen, maintain that cultures of bacillus coli communis, bacillus typhosus and staphylococcus pyogenes aureus, when injected into the tissue of the normal spleen, soon disappear from that organ and, indeed, from the normal body generally. When, however, the vessels have been previously tied these micro-organisms multiply rapidly in the spleen, although those which escape into the circulation are soon destroyed. It is only when lesions have been made in the spleen or any other organ or subcutaneous tissue that these organisms can multiply, and those escaping, as a rule, are rapidly destroyed as they make their way into the blood.

Birmingham Medical Review.—In a paper in the November number on the Treatment of Chronic Disease Dr. Alfred Carter recommends (1) the formation of clinical laboratories where chemical and physiological investigations of cases can be conducted by trained assistants at a minimum cost; and (2) the establishment of fully equipped sanatoria available for the treatment of chronic disease. Under the heading of "A Modern Social Problem" Mr. Henry May, late medical officer of health for Aston Manor, calls attention to the reduction in the birth-rate and marriage-rate and to the "modern undercurrent towards restraint of fertility."

Journal of Pathology and Bacteriology.—In the third number of Volume V., October, 1898, the following papers appear:—Bacillus Coli Capsulatus: a Study in Virulence, by Dr. Louis Jenner; A New Micrococcus, with a Note on the Bacteriology of Lymphadenoma, by Dr. John Hill Abram; Mouse Favus, by Dr. John Hill Abram; On a Method of Estimating the Production of Acid by Bacteria in Nutritive Media, by Dr. William Hanna; The Durability of Passive Diphtheria Immunity, by Mr. Wm. Bullock; A Contribution to the Study of Passive Immunity, by Dr. J. W. W. Stephens and Dr. W. Myers; The Condition of the Salivary Glands and Pancreas in Chronic Tuberculosis, by Dr. Vincent Dormer Harris; Experiments to Determine whether Sewer Air will raise the Toxicity of Lowly Virulent Diphtheria Bacilli, by Mr. Samuel G. Shattock; Molluscum Contagiosum in Two Mated Bunting Sparrows, by Mr. Samuel G. Shattock; Supernumerary Dorsal Fin in a Trout, by Mr. C. G. Seligmann; The Changes Occurring in the Blood of Dogs after Removal of the Thyroid, by Dr. A. G. Levy; Note on the Presence of Iron in the Liver and Spleen in Two Cases of Malaria, by Dr. J. Everett Dutton; On the Effect of Injecting Dilute Sulphuric Acid into the Common Bile Duct, by Mr. Wakelin Barratt; The Effect of Marchi's Fluid on Nervous

Digitized by Google

Tissue that has Undergone Post-mortem Change, by Dr. Frederick E. Batten; The Bone Marrow of Cancer Patients: a Reply to Dr. Francis Villy's First Paper, by Dr. Herbert Snow; A Case of Deciduoma Malignum, by Dr. J. K. Kelly and Dr. John H. Teacher; Laboratory Notes: A Simple Method of Restoring the "Spiking" of the Bacillus Anthracis in Gelatine Stab Cultures and A Modification of Pitfield's Method for Staining Flagella, by Mr. Richard Muir. This number contains much matter of interest alike to the bacteriologist and pathologist and to the physician and surgeon.

Revista Medica de S. Paulo.—We have received several numbers of this Brazilian monthly medical journal, which made its first appearance in the early months of the present year. The opening article of the March number is a Portuguese translation of an address delivered in Italian by Professor Sanarelli on his first experiments on the employment of serum as a remedy and prophylactic against yellow fever. The June number has an illustrated description by Dr. Francisco Fajardo of a hæmatozoon found in beri-beri. The September number contains papers on Yellow Fever by Dr. Vital Brazil, Dr. Victor Godinho, and Dr. Benigno Ribeiro. Dr. Adolpho Lutz has an interesting series of articles on Intestinal Worms and the Diseases produced by Flies in San Paulo. The editors of the journal, Dr. Victor Godinho and Dr. Arthur Mendonça, have made an excellent beginning.

Mercy and Truth.—One of the articles in the November number is Dr. Carr's account of a week's hard riding in Persia, being an urgent journey from Julfa to Kirman, in order to attend the late Rev. H. Carless, who had been taken seriously ill at the latter place.

THE ADMINISTRATIVE CONTROL OF TUBERCULOSIS.

THE QUESTION OF THE COMPULSORY NOTIFICATION OF PHTHISIS.

THE third and last Harben Lecture on Administrative Measures for the Control of Tuberculosis was delivered by Sir Richard Thorne, K.C.B., F.R.S., at the Examination Hall of the Conjoint Board, Victoria Embankment, on Nov. 16th, the subject discussed being the question of the compulsory notification of phthisis.

The lecturer pointed out that a certain number of sanitary authorities had applied to the Local Government Board for their statutory approval to add phthisis to the list of the infectious diseases which are now included in the Infectious Disease (Notification) Act, 1889, but that this approval had never yet been given. He agreed with the action of the central authority, and he pointed out that there was no such similarity between phthisis and the diseases now notifiable—namely, small-pox, scarlet fever, diphtheria, &c.—as would, in his opinion, justify compliance with the demand made. The Notification Act was passed in order to enable authorities to control the movements of persons who for a few weeks only of their lives were in a state which constituted a danger to the public health, such persons being, by reason of a temporary and acute illness unfit to follow their usual avocations or to mingle with others. In the case of phthisis, however, any corresponding sanitary control would often have to be exercised for a series of years, during which time the phthisical persons were not only quite capable of continuing in their employment, but it was often absolutely essential that they should be able to maintain themselves and at times a family as well. The Act was never passed to enable such persons to be subjected to restrictions in the manner intended to apply to the acute infectious fevers. He referred in some detail to the notification of phthisis in New York City because it was often held out as an example to be followed; but he showed that the New York provision has hitherto been most partial in its application, that its operations were in the main limited to persons living in tenement- and lodging-houses, and that apart from this no sanitary control was exercised except with the actual or tacit consent of the medical practitioner in attendance on the patient. Even the statistical results which were quoted in favour of the New York practice showed that the diminution in the phthisis death-rate was in full operation for years before the notification system was established. This was doubtless to a large extent brought about by the same administrative measures which in this country had already led to a saving of no less than 60 lives out of every 100 which at many age-periods were formerly sacrificed to this disease. Instances were then given to show what would certainly follow if the stringency of our laws as to infectious disease were made applicable to this disease. The system of inspection by sanitary officials would lead to publicity and to loss of employment, with the consequent deprivation of food and comforts which are essential to the cure of the disease in its incipient stages, while it would hinder people from seeking medical advice at a time when this was most useful, and thus would defeat the main object in view. It was next pointed out that the same proposal had come before the Academy of Medicine in Paris and that on a report from a committee of that body the system of compulsory notification had been rejected on the ground that it was likely to do more harm than good. The conclusion at which the lecturer arrived did not, however, justify inaction as regards a disease which still caused some 40,000 deaths every year in England and Wales and which is largely spread by means of highly infective sputa which when dried were carried about as dust. The duty of giving to individuals advice as to dealing with these sputa which was likely to be followed devolved, in his opinion, on the medical practitioners whose counsel and help were voluntarily sought by the phthisical patients; and the lecturer appealed to all physicians, whether in hospital practice or in private practice, to give this advice in some such simple form as is to be found in the leaflets now distributed to patients visiting certain of the chest hospitals of the metropolis. Any action by way of notification should, for the present at least, be under a voluntary and not a compulsory system, and such action might well be supplemented by the construction out of public funds of sanatoria for the temporary isolation of persons suffering from this infectious disease, who during their sojourn in these establishments would acquire habits of dealing with infectious materials which would tend to prevent that spread of infection now so largely due to the want of simple and inexpensive precautions. In conclusion, it was pointed out that the success attained under our English system of public health is largely due to the fact that the leaders of that system have been content to lead, and have avoided pressing so far ahead of public opinion as to alienate that support on which success is most dependent.

EAST SUBURBAN MEDICAL PROTECTION AND MEDICO-ETHICAL SOCIETY, LIMITED.—This society is progressing and since the last general meeting in October reported in THE LANCET it has elected about 30 new members. Two council meetings have been held and numerous matters of interest discussed. Action has been taken in 1 gross case of unprofessional conduct and the matter dealt with by the practitioners' licensing body upon evidence laid before it by the society. The Plaistow Maternity Home has sent a favourable reply to the requests of the society for the abolition of midwifery fees by the home, and the representation of the local medical practitioners upon the committee of the home is still under discussion. The debt collecting department has been still further made use of by the members and with success. Sub-committees have been appointed to consider the working of medical aid societies, to arrange for the holding of clinical and social meetings, and to deal with other subjects. Active local branches have been formed at Manor Park, Leyton, Canning Town, and Plaistow, and other branches are in course of formation in other districts. The local branches have also appointed sub-committees to collect evidence and otherwise consider the question of the abuses in local medical charities. The next executive council meeting is to be held on Thursday, Dec. 8th, when the council will proceed to consider *inter alia* the nominations of the officers of the society for election at the general meeting in January. A nomination paper and notice will shortly be sent to all members and they are reminded to return them duly filled in at least two days before the meeting or they will be disqualified.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 26, 1898.

As was to be expected, the new Vaccination Order, with which we recently[1] dealt at considerable length, has given rise to much discussion amongst public vaccinators. The Association of Public Vaccinators has had a largely attended meeting[2] at which it was agreed to forward to all its members certain recommendations regarding fees. The minimum fees for successful vaccination and revaccination are, it is advised by the Association, to be accepted as in the Order, but the preliminary minimum fee of one shilling (Article 3 (1) (*a*) of the Order) is objected to as insufficient, owing to the facts that (as we have already pointed out) this is not really a fee on the birth-rate and that many a domiciliary visit may not result in a vaccination, in which case, of course, the vaccination fee itself will not be payable. Public vaccinators are also recommended to see "that mileage be allowed for at the rate of one shilling per mile, or part of a mile, one way, for distances greater than two miles from the public vaccinator's residence for each statutory visit paid." The public vaccinators of the Bridgwater Union have gone a step further and have petitioned their board for a mileage allowance for all distances over one mile, instead of over two miles as in the above scheme. The purpose of the recommendation of the Association of Public Vaccinators is to ensure that the payment shall vary with the work and that the public vaccinator of a rural district shall have due consideration given to the fact that his duties involve a greater expenditure of time and money than do the duties of a vaccinator in a town district. The object is admirable and we must assume that before issuing the recommendation the Association has satisfied itself that the method proposed for achieving it is feasible. Article 3 (1) of the Order states that the contracts for public vaccinators "shall be made in the form set out in the first schedule hereto, with such modification, if any, as the guardians and the contractor shall, with our approval, adopt." The form contains no blank space to be filled up for mileage fees and no mention of such fees is made in any part of the Order, but the Association may have ascertained that the Local Government Board would be willing to look on such payments as additions to the minimum, and to sanction the necessary modification in the form of contract. We judge the Board's own view to be that the fees for visits and vaccinations should be so fixed in each district as to cover all incidental charges and loss of time, and that it matters little by which method the object is attained.

We have pointed out that the new Order gives no security of tenure to public vaccinators, though it gives very considerable protection to vaccination officers. The evils of the existing insecurity, which will be imported into the new system, seem likely to receive immediate exemplification at Cardiff. The board of guardians there have decided to discharge their present public vaccinators and to appoint in their place one medical man debarred from all other work. Now, if the Order had provided that in future no public vaccinator could either directly or indirectly be dismissed from office without the approval of the Whitehall Department we should have hailed with the greatest satisfaction the prospect of the inauguration of a system of exclusive service, provided such a system were to be introduced without injustice to the large body of medical men already engaged in vaccination work throughout England and Wales. But at present it would be simply illegal for boards of guardians to give anything in the way of compensation or pension to public vaccinators, though their dismissal were for the public benefit as part of an arrangement for the introduction of a better system. To carry out a scheme therefore which involves the dismissal of old servants without consideration would be to inflict great hardship. Still less can it be recommended from the point of view of the men who would take the place of the dismissed public vaccinators. They would have to give up and refrain from all other medical work. They might go on in the vaccination service until middle life or old age, but at any moment, as the result of some whim on the part of the guardians, or on some trumped-up charge of neglect of duty, or through some local election fought out on the question of vaccination, they might receive four weeks' notice that their services were henceforth to be dispensed with, and, probably burdened with the cares and responsibilities of a family, would have to endeavour to find some new employment and to make a fresh start in medical life, handicapped by the fact that their theoretical knowledge of medicine and surgery had long been rusty, and that their experience in treatment had been confined to the rare cases in which vaccinated patients had required a visit or two extra following on their vaccination. We can conceive of no department of medical work in which reasonable protection against dismissal would be more necessary than in a whole-time public vaccination service. The injustice and practical cruelty which have not infrequently been experienced owing to this same want of protection in the public health service are well known. But likely as sanitary work is to be subjected to unfair and capricious local control, vaccination work is in even a worse position and for a medical man to determine to devote his life to an office so precarious would be indicative rather of foolhardiness than of courage.

We do not for a moment deny that a whole-time vaccination service, established under proper conditions, would be a public and a professional benefit. It would give to children and parents the advantage of the highest possible degree of skill and experience—a concentration of thought and attention in all that relates to the practice of vaccination—and it would tend to preserve good relationships between public officials and private practitioners. But the medical profession has already abundantly sacrificed itself, and has already borne sufficient obloquy and abuse, in its determination to protect the population against anti-vaccinationist folly and to succour children against

Digitized by Google

the results of parental ignorance and self-conceit. It is out of the question to expect that if whole-time public vaccinatorships were advertised all over the country to-morrow without a provision for security of tenure the *élite* of the profession would be induced to apply for them. The first step towards the establishment of a proper system is to make it certain that the men appointed shall not be liable to be made the plaything of local feeling, or the victims of prejudiced malevolence. Until reasonable protection is obtained the idea of such a service must be put aside as alike unworthy of the profession and hurtful to the public interest, for it is obviously in the public interest that vaccinatorships should be so conditioned as to attract a thoroughly satisfactory class of applicants. Under existing conditions medical men cannot safely risk more than a part of their time in employment so precarious, and, indeed, the country is to be congratulated on the fact that the medical practitioners who already hold vaccination appointments are so well qualified to fill them, most of them having entered on their work at a time when communities were less exposed to the venom and passion of anti-vaccination crusades. In certain respects the new Order makes an improvement in the position both of public vaccinators and of vaccination officers—a fact on which the Local Government Board are to be heartily congratulated. And those who have experienced the recent evil times have a right to expect that they shall not be deprived of office when its conditions are being more or less ameliorated. But whatever becomes of the proposals for whole-time appointments the official vaccinators throughout the country ought to make a strenuous effort to secure such protection against disturbance as already obtains in some other branches of the public service.

THE Royal College of Surgeons of Edinburgh have presented a memorial to Lord LANSDOWNE regarding the army medical service to which Her Majesty's Secretary of State for War has furnished a very considerate reply. These documents were published in full in THE LANCET of Nov. 12th, but it may be well to recapitulate very succinctly their salient points. The College gratefully acknowledge the interest evinced by Lord LANSDOWNE in the well-being of the service by the constitution of a Royal Army Medical Corps and other beneficial changes; they recognise the importance to the efficiency of the army of having a medical service fully manned and equipped by the best men sent out from the medical colleges and universities and are desirous of encouraging their Licentiates to enter the army. But they point out that certain changes and modifications are still required and might, they think, be advantageously made in the regulations for admission to that service. Scotchmen are an eminently level-headed, practical race and some of the best and most valuable public servants in the world have hailed from the other side of the border, therefore anything which Scotland has to say is always well worth listening to and considering.

The memorial, very pertinently we think, calls attention to the fact that since 1892, by order of the General Medical Council, the course of professional education has been extended to five years, with the recommendation that the fifth year should be devoted to clinical work. The result of this has practically been that the first three years are now devoted to the study of subjects which are the necessary basis of, but which are nevertheless more or less introductory to, medical and surgical science, leaving the last two years to be devoted to clinical work in hospitals and the acquirement of an applied and practical knowledge of the work and duties which have to be discharged as soon as young men are professionally qualified to practise. In the army regulations for the competitive entrance examination too much importance in the opinion of the memorialists is attached to elementary subjects and too little to the practical and clinical work which now occupy the latter years of professional study. Intending candidates for the army competitive examination—who have, it must be remembered, been subjected to a thorough and objective kind of examination on these subjects and have already qualified themselves for the active duties of their profession—are deterred from competing for the army because it either necessitates a return to elementary studies or recourse to a "crammer" to renew and refurbish that kind of knowledge which had been acquired in the earlier stages of their curriculum, whereas the subjects with which the intending candidate has been mainly concerned during the later stages of his career do not occupy the position in the army examination which in the opinion of the Royal College of Surgeons of Edinburgh they should; and they proceed to indicate the direction and lines on which the regulations could in this respect be very advantageously amended. We are very glad to notice, by the way, that the authorities of the College cordially approve of the intimation to medical candidates for the army that they may be rejected for bad spelling or composition. Speaking generally, we recognise the force and wisdom of their reasoning and so, apparently, does Lord LANSDOWNE, although he does not at the present moment consider it advisable to make any change in the subjects prescribed for examination. That a change in this direction will soon be made, however, we have no doubt.

As regards "study leave" for officers of the Royal Army Medical Corps and the constitution of the Examining Board—the other matters alluded to in the College memorial—we think the reply of the War Office is couched in a reasonable and conciliatory spirit. About the importance of "study leave" there cannot be two opinions. Lord LANSDOWNE fully sympathises with the memorialists and has already given his sanction to the grant of leave for the purpose. Owing, however, to the unusually severe demands on the medical service at the present time and to its being so much below its normal establishment it ha not yet been possible to give full effect to this privilege. We are bound in common fairness to say that Lord LANSDOWNE has, we believe, done his best for the army medical service, that he has shown himself well affected towards it, and that, as now constituted, that service merits and should attract the attention of young medical men, offering them, as it does, a good and promising career.

THE *Liverpool Daily Post* recently reported the hearing of a case by the Bootle magistrates in which the vice of drunkenness among women, and its consequences, was

Digitized by Google

illustrated. It was that of CATHERINE HUGHES, who was charged with neglecting her child. The charge was brought by Mr. A. CLEAVER on behalf of the Liverpool Society for the Prevention of Cruelty to Children. The evidence showed that the woman was almost constantly in a state of drunkenness. "She was drinking all day on Monday, and in the evening she was so drunk that she was not even able to arrange the bed that was made up on the floor. A neighbour had to do it for her, and she then lay down with the child, which was subsequently found suffocated." A charge of manslaughter was first made, but was afterwards changed for one of neglect. The bench convicted the woman and sent her to gaol for six months. She had been under the observation of the society for two years. She had been fifty-five times before the court and on four previous occasions she had been charged with neglect of children. The child just suffocated was the only one left in her charge.

We direct attention to this case both for its own sake and because it graphically illustrates the bearing of the drunkenness of women on the domestic life of the nation and especially on the care of children. The woman on one occasion could not make her bed because she was so drunk and on the death of her child she was "in such a state" that she fell over the dead body. It needs little imagination to conceive what chance of care and proper feeding a child in such a home has. As a matter of fact, the law had removed the other children from her care and stepped into the place of the parent. To afford even obtuse people a clearer view of the home of a drunken woman we may give a short account of a visit paid to it by Inspector WILLIAMS, who had been watching the prisoner for the Liverpool Society for the Prevention of Cruelty to Children. Since 1896 "Mrs. HUGHES occupied the back room, which was practically destitute of furniture, with the exception of a table, a basket, and a shakedown on the floor, while the windows were broken and filled up with old sacking. The apartment was in a filthy condition, and on that occasion the woman was sitting on the basket helplessly drunk with the baby in her arms. ..... He spoke strongly and warned her. He returned about a week afterwards and again found her under the influence of drink." Can anything be more vivid or call more loudly for the attention of the State and of the municipal authorities? Here was the chance of every accident—such as fire, falls, filth. Here was the certainty of improper food. How could wholesome milk be forthcoming when so large a proportion of the income was spent on drink and in producing maternal incapacity? In the end this particular child died—doubtless was killed—before the State came to its assistance. In the case of the other children the conditions were so shocking that the State had intervened and assumed parental responsibility. What do the advocates of freedom as against sobriety say to a case like this? They say, of course, that it is an isolated case. But is it really so isolated as they contend? There is far too good reason to believe that it is not so. The drunkenness of women is forced upon our attention in every newspaper and in passing every public-house. Old men say that there was nothing in their younger days to correspond with the present unblushing use of public-houses by women, who seem to vie with men in their visits. We need not labour the proofs of an evil so obvious. But the case before us shows us the meaning and the result of such habits in women. As long as the woman keeps sober and "at home" there is a chance for that home. Even if her husband has a tendency to alcoholism her presence and the comfort of his house under her care is a restraining influence for him. But if she takes to drinking and the public-house the case is well-nigh hopeless and in a degree it will approach to that of CATHERINE HUGHES. The State cannot escape responsibility. If it is not to accept the parental relation to the children of drunken parents in a very large number of cases it will have to consider what help it can give to weak parents against an influence which experience shows to be well-nigh irresistible and which the law has in past times too little restrained. Medical men, perhaps, of all others, have the best means of knowing the urgency of this evil of the drunkenness of parents and are most entitled—are, indeed, bound—to make it clear to the public mind.

In connexion with the above remarks we are glad to note that at a recent conference on public health in Manchester Dr. ASHBY, whose authority on the subject will be admitted, has directed attention to the rate of mortality amongst the children of the lower classes. In Manchester it is very serious. Dr. ASHBY is physician to a children's hospital with a dispensary department in Manchester. Of 10,000 cases admitted into this institution 4000 were those of children under ten years of age. Of the deaths, 85·5 per cent. were those of children under two. Dr. ASHBY says that the death-rate of children in Norway and in the rural parts of England is at the rate of 100 per 1000 births, while in Manchester it is at the rate of 203 per 1000, and in some of the congested districts, where poverty, drunkenness, and vice abound, it amounts to 300 and even 500 per 1000—something like one half of the infants born dying before attaining the age of one year. This is a scandal to the municipal authorities and to the State. As a profession we cannot be too careful to expose it and to wipe our hands of all responsibility for it. Dr. ASHBY has done his part and he attributes this infanticide to artificial foods, bad milk, and infant life insurance. Very many of the children who die prematurely are insured. Of 155 who died 105 were insured, and in about one-fifth of the insured cases the payment was made wholly or in part in drink by clubs in public-houses.

THE subject of the appointment of county medical officers of health which has been raised from time to time is once again under discussion. It is now ten years since county councils were constituted by Act of Parliament and since they received statutory power to appoint and pay county medical officers of health, and yet only 16 out of 51 administrative counties have availed themselves of this power. Many county councils complain somewhat bitterly that their sanitary functions are few and far between and that if Parliament had passed the Local Government Act, 1888, in the form in which the Bill was originally drawn up there would then have been good grounds for the appointment in all administrative counties of a medical officer of health. There is truth in this contention, but it is a somewhat curious fact that some of the most frequent complaints which county councils make as to the

Digitized by Google

failure of local district councils within their areas to perform their statutory duties in matters relating to public health are concerned with duties the performance of which has not been made obligatory; and yet the county councils themselves fail in precisely the same way, for the appointment of county medical officers of health has been made a statutory duty but not a statutory obligation.

Thus, county councils are empowered to make "representations" to the Local Government Board as to default on the part of the local councils, and a very frequent cause of complaint at one time had to do with the failure of the local authority to provide means of isolation for infectious patients. But the local authority stands in precisely the same position as regards hospital provision as does a county council in the matter of a medical officer of health. In both cases statutory provision has been made as to a matter that is an obvious duty in the interests of the public; but in neither case has that duty been imposed as a matter of absolute obligation. Another somewhat common ground for making a "representation" is concerned with the failure of local authorities to deal efficiently with the removal of refuse and the excreta of the population, and appeals are made by county councils that the Local Government Board shall by order require this matter to be dealt with by the local authority instead of its being left to owners and occupiers. But this again is a matter which apart from the issue of such an order is left to the discretion of the local authority. Indeed, it seems strange that county councils who are so alive to the failure of the authorities within their jurisdiction in matters concerning which they have no definite obligation should be so blind to their own failure in precisely the same direction.

Whilst, however, we point to such activity of county councils in making complaints, it is a matter of general experience that in those counties where no health officers have been appointed there is an extraordinary laxity in matters relating to the public health. We might place, for example, at opposite poles some of our northern administrative counties such as Lancashire, Durham, and the West Riding, where county health officers have been appointed, and Somerset, Devon, and Cornwall where no such officers have been appointed. From the former have come well-formulated representations based on the results of an inspection of the sanitary circumstances of the districts within the counties, and these representations have always received the attention of the central authority, with the result that great gain has been effected and that the public have benefited. From counties like those in the latter group there have, we believe, been some querulous complaints based upon something that a local district health officer has written to his own council, or on something which a compiler of reports has summarised for the county council; and so far as we know no action beyond the writing of a few letters has ever resulted. Indeed, it is difficult to conceive how the matter could well have been otherwise, for it is hardly likely that a Government department would support the views or opinions of a county council which, for the purposes of economy, has never taken the means to ascertain for itself the facts about which it makes complaint. When such county councils act up to the powers already conferred upon them, then it will be time enough for them to ask for further powers.

Since the passing of the Local Government Act of 1888 another Act has been passed enabling county councils themselves to intervene in the matter of the erection, for combined areas, of hospitals for infectious diseases, and a very strong indication has been given to county councils in this Act to the effect that they are not deemed competent to perform their sanitary functions in this respect, at least, until they have appointed a medical officer of health, their intervention being practically limited to the receipt of a report from their medical officer of health on the subject. But even this strong hint has been largely ignored; and county councils still refrain from undertaking this elementary step in the direction of efficient sanitary administration, although a few have tried to get out of the difficulty by paying some medical practitioner to act as their medical officer of health for certain odd purposes, the officer having a small retaining fee and being at times called on for a report on some special subject.

The latter class of officer has, we need hardly point ont, absolutely no weight in the county; his intervention is often resented by the local medical officers of health, and the counties where such an arrangement has been made are practically in the same position as those where it has not been thought worth while to make any appointment to the office. But when a county health officer has been appointed at a salary which justifies the demand for his whole services for county purposes the matter is quite different. Such an officer is often sought out by the district health officer to give the weight of his county and independent influence in the furtherance of an object about which there are small local difficulties and jealousies which make the local officer practically helpless. Such county health officers, again, can take cognisance of a number of matters which affect multiple local districts but which the local health officers can only deal with up to the boundaries of their respective districts, or cannot deal with at all because they involve areas over which they have no control. In short, properly appointed county health officers have already shown that it is a distinct advantage to the public that appointments such as theirs should be generally made, and in the face of the facts that are patent to those who know what has been done no real object is gained when chairmen of certain county councils declare that it is nugatory to make these appointments until more sanitary duties are devolved by statute on the counties. The truth is that some of the county health officers have to do already more than they can. In the West Riding of Yorkshire, for example, it has been found necessary to hand over the question of river pollution, which was formerly dealt with by the county medical officer of health, to an entirely independent officer.

Now that this subject has once more been raised it is to be hoped that proper consideration will be given to it. But it is not a mere appointment that is wanted: the post must be properly constituted. Parliament has already decided that a county health officer must have special statutory qualifications; it is equally important that he should receive an emolument that will give him the necessary status of a county official. This requirement is in some cases being ignored. Thus, when a sum of £500 a year is bestowed on

Digitized by Google

such an officer, one of two things must necessarily arise. Either the officer cannot, on such a salary, maintain for himself the position which is necessary to his proper influence, or else he will at the first opportunity use his appointment as a means of securing another one which is more adequately remunerated. In other words, just when he has acquired the local knowledge and experience necessary to the proper performance of his duties he will resign and the county will be handed over to a new official who will have to pass through the same training as his predecessor before he can attain the same position of usefulness and influence.

"Ne quid nimis."

THE ACCIDENT TO THE PRINCE OF WALES.

IT is with much satisfaction we are enabled to inform our readers that His Royal Highness the Prince of Wales has now made an excellent and, we may really say, complete recovery from the severe accident which he met with in July last, and after the interval which has elapsed of more than four months the cure may be reasonably considered permanent. It will be remembered that while descending a spiral staircase the Prince missed his footing and the extreme effort which he then made to recover his balance caused a rupture of the insertion of the left quadriceps extensor muscle which tore away with it at the same time the upper portion of the patella. At present the nature of the union which has taken place leaves little or nothing to be desired. The fragments of bone were separated by a considerable interval which gradually became reduced and the gap is now completely filled with strong fibrous material which shows no sign of stretching and has throughout been carefully prevented from yielding. Massage of the limb and passive movement of the joint were begun at a very early stage and have been followed by the happiest results. The knee readily bends to considerably more than a right angle and the power of active extension at the joint is very good indeed. The Prince can readily go up and down stairs, and can walk with ease and comfort and with a scarcely perceptible halt which is, moreover, only due to the slight embarrassment to the joint movement caused by the light splint which he is wearing and will continue to wear for a few weeks longer as a matter of precaution. So far as the injured limb is concerned His Royal Highness will be able to use it in all his many occupations as well as he did before he met with an accident which is not infrequently followed, as we know, by serious consequences to the usefulness of the extremity.

THE FEEDING OF OUR SCHOOLBOYS.

THE question of the feeding and health of boys in connexion with the public and other large schools in this country has of late been occupying a good deal of attention. It is, of course, very difficult to get at the exact truth in a matter of this kind, but there cannot be a doubt that complaints about school dietary are very common. From inquiries we have instituted we have arrived at the conclusion that these complaints as to the quantity, quality, variety, or cooking of the food supplied at such schools are too numerous for them all to be considered unreasonable or unfounded, nor are we satisfied that, in point of time, the daily meals are always as well distributed as they might be. What is strongly corroborative of there being something faulty in the system is the fact that boys very frequently spend their money in the purchase of such food as bread-and-cheese and bread-and-butter, and not in the various small luxuries that commonly prove so tempting to schoolboys. It would surely be easy to ascertain by inquiry as to how the boys actually spent their pocket-money whether this were the fact or not. If it be spent in the purchase of ordinary articles of diet the inference would be that they had to supplement their school dietary to make it sufficient. But it is not after all, we believe, so much in respect of the quantity as in the cooking and carving of the meat supplied at schools that there is legitimate ground for complaint. The cooking is commonly bad or uncertain in character and the carving is also such as to lead to a wasteful and unequal distribution of the food supplied. The whole subject is well worthy of careful inquiry and practical consideration on the part of schoolmasters. For years the dietary and cooking for the soldiers of our army were badly and uneconomically managed until they were practically taken up and reforms were introduced with very great advantage to the soldier; and similar results would probably follow in the case of public schools if the systems of dietary and cooking were made the subject of investigation by men practically acquainted with the matter.

INSTRUCTION IN TROPICAL MEDICINE.

LAST week we briefly referred to some of the objections which might be raised against the scheme of establishing a School of Tropical Medicine at the Branch Hospital of the Seamen's Hospital at the Royal Albert Dock. The committee who are at present conducting the preliminary arrangements propose to concentrate the teaching material at this branch, meaning thereby keeping the cases at the branch instead of sending them to the parent hospital at Greenwich. The Branch Hospital was built as an emergency hospital and was never intended for the reception of any cases which could be allowed to cross the river. Last week we instanced the futility of such a proposal by pointing out that in 25 years only 50 cases of "tropical abscess" had been received at the hospital and on further studying the "tables of cases under treatment at the hospitals and dispensaries of the Seamen's Hospital Society in 1895 and 1896," we are at once struck with the very small number of patients suffering from "tropical diseases" who have been under treatment. Amongst the general diseases we find 73 cases of malarial fever and 2 of bubonic fever but no other recognised tropical fever. Amongst diseases of special organs or tissues there were 44 cases of beri-beri and 4 of "hepatic abscess." Where, then, are the tropical diseases? The explanation is obvious. The acute cases either die at sea before they can reach the hospital or are of an infectious nature. In the former case they will not be available for "concentration," and in the latter the port sanitary authorities would interfere to prevent such "concentration." On the other hand, the Seamen's Hospital would seem in a great measure to be an asylum for sick sailors, for there were in the period stated 221 cases of pulmonary tuberculosis, of which 73 proved fatal, and of these 1 was in the hospital over 600 days, 5 were in over 300 days, 2 over 200 days, and 15 over 100 days. Whilst, therefore, fully desirous that support should be given to Mr. Chamberlain's scheme we cannot but wonder how he came to be advised to select the Branch Hospital at the Royal Albert Dock as the nucleus of the school. Further, it is intended that laboratories should be equipped at the new school for the purposes of research. But surely that is unnecessary. Laboratories already exist with every requisite appliance for such work on the Victoria Embankment, at Chelsea, and at certain metropolitan medical schools. Here qualified medical men already attend from all parts of the world, such

Digitized by Google

as Uganda, West Africa, Australia, Canada, &c., and diseases of tropical climates—such as malaria, leprosy, plague, cholera, Madura foot, &c.—have especially been made the subjects of original research. A knowledge of bacteriology is essential to colonial practitioners, but we doubt whether anything would be gained by the establishment of new laboratories, as is laid down in the scheme for the new school. There is another aspect in the present management of the proposed school to which we must refer—namely, the conduct of the committee towards the honorary staff of the *Dreadnought* Hospital at Greenwich. Sir Henry Burdett, in his letter to the *Times* of July 11th, stated that "the teaching staff will consist of the senior medical staff of the *Dreadnought* Hospital at Greenwich, as well as of the Branch Hospital, together with a number of teachers specially selected and attached to the new school." A few days later, however, a letter appeared in the same journal, signed by Dr. Curnow and Dr. John Anderson, the physicians to the hospital, and Mr. G. R. Turner, the surgeon, stating that Sir Henry Burdett's letter was the first intimation of any kind that they had that such a scheme was on foot, and that the statement was made without their authority. Such conduct on the part of the committee certainly needs an explanation, for on the face of it but scant consideration has been shown towards Dr. Curnow, Dr. Anderson, and Mr. Turner. At the last meeting of the Comitia of the Royal College of Physicians of London a letter was read from the Seamen's Hospital Society "asking the College to nominate a representative" on a committee appointed to organise a School of Tropical Medicine in connexion with the Branch Hospital. After some remarks, however, from Dr. Curnow and Dr. Anderson, the "previous question" was carried—an act of great significance as tending to show that without further explanation the College was unwilling to be represented on the committee.

THE INTERNATIONAL CONGRESS FOR THE SUPPRESSION OF ANARCHISM.

LUCCHENI, anarchist and assassin, has been condemned to life-long seclusion with hard labour—a sentence which John Stuart Mill thought so much severer than capital punishment that in the House of Commons thirty years ago he voted against the abolition of the latter on the ground of its greater humanity—and so from at least one active instrument of social chaos and destruction the world is now free. We have referred in a leading article in THE LANCET of Nov. 19th to the "anthropo-psychiatric" view of the case, but what of the organised conspiracy of which he was a member? Is civilisation to look idly on and let the anarchist propaganda extend and multiply proselytes? Is it only to drop its inertia when the head of a state or the scion of a royal house is done to death? The answer is an emphatic negative and comes appropriately from the Italian Government under which the conspiracy itself takes most congenial root and rears the most daring executants of its decrees. In the present week, accordingly, in Rome and on the invitation of the Minister of Foreign Affairs (Signor Canevaro), the European Powers, through their delegates, are assembling in the Palazzo Corsini to consider the best means of wiping out what Lord Salisbury calls "this monstrous affliction of humanity." The hall in which the congress meets is itself significant of the many interests which combine to inspire its deliberations. It is that in which the Accademia dei Lincei (the Italian Royal Society) holds its sittings and it has been watched and guarded with a precautionary vigilance which shows what scant consideration the anarchist is known to have for science and its treasures any more than for human life when they come between him and his fiendish purpose. The Prefect of Rome and the Questor (head of the police) have had all the substructure of the palace minutely examined and a special "surveillance-service" will be maintained over the building and its representative inmates till the proceedings have closed. Lord Salisbury indicated that with every wish for the Congress to attain its end he had little expectation of its doing so; and his lordship is justified in the remark. None know better than the British leaders of hygiene how difficult it is to get foreign Powers to agree as to the best mode of meeting a threatened epidemic. At the conference, for example, held in Rome some thirteen years ago to concert measures against the advance of cholera, the representatives of the southern Powers were unable to look at the question from the same point of view as their brethren from the north. They insisted on regulations and restrictions which would have made the remedy worse than the disease, while their whole habit of thought and of legislation was utterly opposed to what in Great Britain is regarded as lawful and sound. Instead of setting their own houses in order and keeping off disease by denying it the pabulum on which it feeds, they could think of nothing but quarantine or sanitary cordons, and while their ports were inviting the foe by their defective hygiene they were contented by creating artificial barriers to its approach which, even if effective, would have cost civilisation and its forces too dear. We venture to predict that the experience of our own delegates at the Anti-Anarchic Congress will be similar to that of their sanitary predecessors thirteen years ago. These same southern Powers by their misgovernment, their "bloated armaments," their intolerable taxation, their scant employment for the wage-earning poor and the hardness of living thus induced are themselves the fosterers, if not indeed the parents, of the social malady which they are seeking to suppress. But rather than reform or even abate the above sinister conditions they will devise and propose systems of surveillance and modes of repression which more healthily constituted Powers can neither approve nor adopt. It was this doubtless which Lord Salisbury had in view when he indicated how little hopeful he was of the success of the congress. It will not, however, have met in vain if its discussions should put in clearer light the economic and social abuses by which anarchism seeks to justify itself, if, indeed, it does not spring from them. The Italian press has recently been dealing with M. Moriand (Luccheni's counsel) and his contention that such privations as those to which Italy subjects her poor cannot but be prolific of the desperadoes who swell the contingents of lawlessness and crime. The more candid of her organs, indeed, admit the justice of the Swiss advocate's plea and contrast the misery prevalent south of the Alps with the contentment so visible on the north. They are beginning to appreciate what the professional classes in the kingdom—above all, the medical men—have long been advocating and fighting for: the enlargement of the resources of education at the expense of the merely combatant interests; the deflecting of the country's means and energies from the military and naval establishments to the schools primary and secondary and in the last resort to the Universities. This is a large programme, not to be carried out in its integrity but after much controversy in the constituencies and in Parliament. But it is one in which the welfare of Italy in particular is vitally involved, if she is not to be added to the list of those "decaying Powers" on whose "manifest destiny" Lord Salisbury discoursed so wisely and so well.

A CURIOUS CASE OF PHOSPHORUS NECROSIS.

A CASE of phosphorus necrosis due apparently to the inhalation of phosphorus fumes is recorded in a recent issue of *L'Odontologie*. The patient was a man, of good health, but addicted to the habit of excessive cigar-smoking,

Digitized by Google

consuming about 20 cigars a day and using many matches to each one, as he frequently interrupted the smoking during his work. It was computed that for the last 20 years he had daily inhaled the vapour of phosphorus given off by over 100 matches. The early symptoms were pain in the right eye, with swelling involving the whole side of the face. Suppuration supervened and the pus obtained a free flow into the oral cavity. The patient's condition grew worse and the maxilla was eventually removed. A few months later a fresh operation was necessary, but the patient collapsed dying from meningitis. The patient's teeth were in a deplorable condition, so that it is possible the phosphorus acted through the medium of the teeth as the cause of the necrosis.

"ANOTHER STREET DANGER."

IN an annotation under this heading in THE LANCET of Oct. 22nd we drew attention to the dangers which arise from the use of "flash-light" advertisements—advertisements, that is, which are alternately displayed and withdrawn by the turning on and off of a strong light—in the streets of London. Our attention was called to the matter by a report of an inquest on the body of a woman who was run over by a coal waggon at Kilburn. In this case it appears a horse had taken fright at one of these advertisements displayed in a first-floor window. The driver lost control of the animal and the woman was killed. In giving their verdict of "Accidental death" the jury added a rider protesting against the use of advertisements manipulated in this way. With this protest we expressed our hearty agreement, and it seems worth while to point out with greater fulness the nature and extent of the dangers which may arise from these inventions. These advertisements are often lighted by powerful electric lights and during the ten or twenty seconds in which the lights are turned on they brilliantly illuminate the part of the street in which they are placed. Suddenly this brilliant light is turned off and the streets are left in that condition of semi-darkness which the nearest gas lamp is wont to produce. The result of this sudden transition is obvious. If we suddenly pass from brilliant sunshine into a dimly-lighted room it is a matter of common knowledge that for the first half-minute or more we are quite unable to see anything. The eye takes an appreciable time to accommodate itself to the altered conditions in which it finds itself and fails to distinguish objects which after a moment or two it can discern with comparative ease. So it is with these most dangerous advertisements. For a few seconds everything is as bright as day. Then in a moment we plunge into what appears to be complete darkness. If we are so unfortunate as to find ourselves in the middle of the roadway when the light is turned off we have an excellent chance of never reaching the pavement except on a stretcher. The foot-passengers cannot see; the drivers cannot see; the horses cannot see, and, moreover, they are often rendered nervous by the sudden change from light to darkness, as seems to have happened at Kilburn. And if any one is run over it is difficult to apportion the blame. It may be urged that there is a remedy at law. If such a light is a nuisance and a danger an injunction could be obtained against its use. But this, after all, is an unsatisfactory method of safeguarding the public. It is not easy to find a man sufficiently public-spirited—or sufficiently litigious, if the term is preferred—to spend time and money upon a lawsuit to abate a nuisance from which other people suffer equally with themselves. Most people will prefer to run the risk or—if they are timid folk—will choose another place for crossing the road. But is it not rather ridiculous that the inhabitants of London and any other large town where these irritating advertisements are permitted should not be able to use their own streets in comfort and safety without such precautions? We should like to have the opinion of the policeman on duty at some point where a flash-light advertisement is in operation as to the additional difficulties which it causes him. A constable on duty, say at the top of Sloane-street, has none too easy a task in regulating the traffic even when all the conditions are favourable and he has a steady light to see by. But place him at intervals of twenty seconds in the full glare of a powerful electric light and then in what appears by contrast to be total darkness and he is practically helpless. A man cannot regulate the traffic when he cannot see it. And yet this very point, the top of Sloane-street, a narrow and very crowded thoroughfare where several lines of traffic converge, has been selected for one of these electrically lighted advertisements. It seems to us astounding that such a state of things should be permitted. It should be possible to find methods of advertising a tobacco, a beef tea, or a patent medicine, which are not actually dangerous to the safety of the community. We imagine that this aspect of the case has not struck the firms who make use of this method of calling attention to their wares. If this is so it is hardly too much to hope that the perils of the system, emphasised as they have been by the death from this cause which occurred so recently at Kilburn, will cause them to withdraw such advertisements altogether.

BILE PIGMENTS.

THE results of an elaborate series of researches on the bile pigments in the higher animals and in some of the invertebrates have been recently published in the *Archives de Physiologie* by MM. Dastre and Floresco. These experimenters started with the intention of demonstrating that biliprasin pigment, which it will be remembered was originally obtained by Städeler from gall-stones, corresponds to an intermediate stage between the two chief pigments, bilirubin and biliverdin. The experimenters arrive at this conclusion from an examination of the effects produced by oxidation in the air, those produced by oxidation by means of iodine, and those resulting from deoxidation owing to exposure in a vacuum. They have satisfied themselves that bilirubin—i.e., bilirubinic acid— does not exist free in bile, except perhaps in some strongly pigmented kinds of bile, as that of the pig, but that it is in combination with sodium as a neutral bilirubinate, for bilirubin is insoluble both in normal bile and in the decolourised bile of Plattner; moreover, the alkaline bilirubinates, contrary to the statement of Städeler, are only to a small extent soluble in water, whilst they are soluble in the alkalies and in the alkaline carbonates. Bile is, in regard to the nature of its fundamental pigment, a solution of sodium bilirubinate in the alkaline carbonates. The second principal pigment, green pigment, biliverdinic acid, is in similar case. It is, however, slightly soluble in normal bile and in decolourised bile, whether neutral or acid. It exists in the bile principally in the state of sodium biliverdinate dissolved in the carbonates. Solutions of bilirubin do not absorb oxygen from the air to pass into the condition of biliverdin. This absorption only occurs with the bilirubinates in becoming biliverdinates. The colour of solutions of the fundamental pigment depends on the quantity of the pigment and varies from a deep red containing $\frac{3}{1000}$ths or more to a pale yellow, which is always the colour of neutralised solutions. In normal bile taken from the gall-bladder MM. Dastre and Floresco have discovered two other intermediate pigments which they have named biliprasinic pigments. One of these is of yellowish brown colour and is the biliprasinate of soda. It is converted into biliprasin or green pigment by a current of carbon-dioxide and by acetic and most other acids, especially in presence of alcohol. It is not stable *in vacuo*, being decolourised

Digitized by Google

by the action of light, and when exposed to air and light it becomes green (changes to sodic biliverdinate). It is this biliprasinic pigment which gives its yellow colour to the bile of the calf, but it exists in other yellow biles. The second biliprasinic pigment is a green pigment; it is biliprasin. It differs from biliverdin—i.e., the biliverdinates—in becoming yellow (forming biliprasinate) on the addition of a few drops of alkali, and in becoming red (forming bilirubinate) on exposure to a vacuum. It is slightly soluble, especially in liquors charged with CO_2. It constitutes the ordinary pigment of the bile of the calf, of the fresh bile of the ox, and of the bile of the rabbit. The relation of the two pigments to one another is very simple. The yellow pigment is an alkaline salt of the green pigment. They are converted into each other by the alternate action of acids and of alkalies; thus, the acid forms one pigment, the alkaline salt another. This is in opposition to what occurs with bilirubin and the bilirubinates which are equally yellow, and with biliverdin and the biliverdinates which are equally green. Hence, contrary to what is usually stated, yellow bile can become green without oxidation. True biliverdin is less common than is supposed in bile. The biliprasinic pigments are intermediate to the fundamental pigments, bilirubin and biliverdin, in point of oxidation and of hydration. Those processes affecting the original fundamental pigment of the bile, bilirubin, commence possibly in the hepatic cellules and in the biliary ducts and certainly go on in the gall-bladder, but the artificial conditions for this change are not here realised. Hence the hypothesis of an agent or condition for inducing oxidation (hepatic oxidasis). In the invertebrata MM. Dastre and Floresco distinguish pigments soluble in water and pigments soluble in chloroform. The pigment soluble in water is named by them "ferrine" and contains iron combined with some proteid. The pigment soluble in alcohol and chloroform contains no iron and is identical with cholechrome. It has a spectrum with four bands and appears to be identical with the chlorophyll of plants.

THE COLOUR OF NEWLY-BORN NEGRO CHILDREN.

AN article appeared in the July issue of *Pediatrics*, commenting on the statement of the French physician, Dr. Farabery, that negro children when born are of exactly the same colour as are those born of white parents. The writer in *Pediatrics* quoted Dr. Farabery's assertion that he had had ocular proof of this fact at the Soudanese Exhibition held in the Champs de Mars, Paris, where he had seen negro infants up to the age of seven days and, in some instances, to a considerably later period, who were similar in every respect to white infants. The article in *Pediatrics* has called forth many letters from medical men practising in the Southern States of North America where the black race abound. They one and all stoutly deny the truth of Dr. Farabery's assertion, although it is somewhat curious to notice that they are not agreed as to the exact colour of the negro newly-born infant. For instance, one gentleman writing from Birmingham, Alabama, says: "I have been actively engaged in the practice of medicine, including obstetrics, in Alabama, without intermission, since the spring of 1886. Many others have had an equally large and ample experience to assume the attitude of authority on the subject under discussion, and our deductions would be that babies born of negro parents are black; some of them very black, others not quite so black as they get to be later. Those born of mulattoes, or mixed blood, vary according to the predominance of the white or black race; but however light the general surface may be, if negro blood exists the scrotum in the male is usually black, the female genitals do not show such distinguishing features so clearly." Another medical practitioner, living in New Haven, Missouri, writes thus: "Our experience tells us that the newly-born negro child is not of exactly the same colour as its white brother. The 'exhibition in the Champs de Mars' could not convince us against facts which have come under our own experience for many years. The colour of the newly-born scion of African parentage, whether of immediate or remote descent, is not the same as that of the Caucasian or American. It is a sallow or creamy white without the pink glow or tinge that marks the scions of Caucasian origin. We must take issue with the French physician that there ever appears 'a tender pink colour' if the slightest trace of African or negro blood is present. The 'tanned leather,' familiarly known as 'saddle colour,' belongs exclusively to a mixture of the white and black races. The pink rosy hue of the cheek of the Caucasian never has been seen in the cheeks of those having even one-eighth of negro blood in their veins." Here are three different opinions with regard to the colour of the newly-born negro. Dr. Farabery says that it is exactly like that of a white infant up to seven days old; the American doctor from Alabama says that it is always black; while his fellow-countryman from Missouri says that it is sallow or creamy white. The question is—who is right? There can be no doubt that from their greater experience the dictum of the American medical men is worth more than that of Dr. Farabery, but even they do not agree. It would be interesting to hear what practitioners in our African colonies and Egypt have to say on the matter. The Rev. J. G. Wood, in his "Natural History of Man," remarks: "As is the case with the negro race the newly-born infant of a Kaffir is nearly as pale as that of a European, the dark hue becoming developed by degrees." It surely would not be difficult to clear up this point.

SERUM *v.* VACCINE IN PESTIS BUBONICA.

PROFESSOR ALESSANDRO LUSTIG, director of the pathological laboratory attached to the Florentine School of Medicine, endeavours to dissipate the erroneous views which he finds prevalent, particularly in Continental Europe, on "serotherapy as contrasted with vaccino-prophylaxis" in pestis bubonica. The first serum used in Bombay, he says, was the French (Yersin), and that only in a limited number of cases during the epidemic of 1896-97. This, according to the official report printed in 1897, gave but poor results in the human subject—a finding subsequently confirmed by Koch. This was followed, in 1897 and in a limited number of cases, by the serum prepared (on a very different method from the French) in the Florentine laboratory. It succeeded in Bombay and at Poona in reducing the mortality in hospital to 40 per cent., while among the patients not so treated the deaths were 86 per cent. Coincidently with these experiments trial was made of the serum prepared at St. Petersburg on the Yersin method, with a mortality officially given as 82 per cent. In 1898, on the recrudescence of bubonic plague, there were made, almost contemporaneously and in the same hospitals, experiments with serum prepared on three different methods: (1) the Haffkine serum, giving a mortality of 82 per cent.; (2) the serum prepared in Russia on the Yersin method, yielding identical results; and (3) the serum prepared in Florence, reducing the mortality to 46 per cent. This last serum, which is hitherto the only one which has been systematically tried in several hundreds of cases, is now under the charge in Bombay of Dr. Gino Galeotti and Dr. Giovanni Polverini, of the Florentine school, who carry on their work in a laboratory fitted up for this purpose by the Bombay sanitary authorities. "To omit nothing," continues Dr. Lustig, "I may mention that towards the defervescence of the last epidemic, trial was made

Digitized by Google

of the French serum, not, however, in the hospitals, but only in isolated and distant centres. Of this the official report has yet to appear. Great confusion of thought," he adds in words which we translate textually, "is prevalent as to 'vaccine' and 'serum,' and so we often see mention made of the 'Haffkine serum,' instead of the 'Haffkine vaccine.' Now, Haffkine is a Russian physician who at first prepared a serum which proved inefficacious and who at present undertakes in India preventive vaccination—that is, inoculating the healthy subject with attenuated bacilli of the pestis. This practice appears to give good results, but the efficacy of a prophylactic means is determined with difficulty. We can pronounce better on a curative procedure, especially when the mean death-rate is very high. In any case this vaccinal treatment is not to be confounded with serotherapy, as is constantly done in the lay press."

THE DANGERS OF IRRIGATING EMPYEMATA.

IN the *American Journal of the Medical Sciences* (October, 1898) Dr. E. G. Janeway relates the following case. A man who had been operated on for sacculated empyema used to irrigate the sac with hydrogen peroxide. One day, three and a half months after operation, two minutes after the injection of a wineglassful of the peroxide he felt very peculiar and became for a second unconscious and of a pale greenish colour. He then found that his right arm and leg were numb and powerless; this condition lasted for twenty-five minutes. Three days afterwards he had an exactly similar attack except that also he lost power in his neck, his head drooped, and he had difficulty in breathing. The occurrence of serious nervous symptoms on irrigating empyemata has been noticed by several. M. Bonveret, in his work on Empyema, published in 1888, collected a series of such cases which he has grouped under the head of Embolic, Slow Paralytic, Syncopal, and Convulsive. The following case, published by Leudet, is somewhat similar to the one just described. A young man had the sac of an empyema regularly irrigated with a solution of iodine. On one occasion he was suddenly seized with malaise, a sensation of numbness in the right side of the body, and loss of speech. Gradually power of motion returned. Two attacks of the same kind occurred later. Afterwards this irrigation was continued for a year without further accident. Dr. L. Forgues relates another case in the *Archives de Médecine et Pharmacie Militaires*, 1894. During the irrigation the patient suddenly became unconscious, with pale face, cadaveric look, open eyes, and dilated pupils. Heart-beat and respiration were suspended. After cold flagellation they returned in about a minute. When the patient became conscious the right arm and leg were paralysed. After twenty-five minutes power returned to the right leg, but it was three hours before the right arm could be used. In our own literature, which Dr. Janeway seems to have overlooked, similar cases are recorded. In the Transactions of the Clinical Society, 1877, Dr. Cayley has recorded the case of a man who had an empyema repeatedly washed out. One day this was followed by convulsions, opisthotonos, and death in sixteen hours. In THE LANCET of March 17th, 1894, Dr. Fisher has published a case where collapse and hemiplegia occurred during perflation of an empyema. In THE LANCET of May 4th, 1895, p. 1101, Mr. Stephen Paget mentions a number of cases and also the case of a child who died at once after a cold lotion had been used to irrigate an empyema. What is the explanation of these accidents? Dr. Cayley and Mr. Paget regard them as so far unexplained. To the theory that they are due to cerebral embolism, from passage of some substance into the circulation during the irrigation, which naturally suggests itself, there is the objection that in fatal cases no cerebral lesions, embolic [or other, have been found. Dr. Janeway, however—and it seems quite rightly—adopts the embolic theory as the only one which can account for the hemiplegia. He supposes that the emboli are of such a nature as soon to disappear—air or gas. He remarks that the symptoms occurred when the conditions were such as to produce pressure in the sac: the liberation of oxygen from peroxide of hydrogen; the measuring of the sac; changing of the tube; and pressure to hold the tube in its place. In support of this view he refers to Professor Lewin's experiments where death was produced by injecting air into the bladder, the air entering the venous system through the pelvis of the kidney. However, is not an alternative explanation tenable—that the emboli are solid particles so small as to have been overlooked at the necropsies? Dr. Samuel Gee, writing in Allbutt's System of Medicine, condemns injections in the treatment of empyemata as dangerous. He attributes the serious and fata consequences which may ensue to syncope, the cause of which is not understood. He refers to a fatal case in which the right cavities of the heart were found distended with gas, which supports Dr. Janeway's hypothesis.

A MEMORIAL TO THE LATE DR. BARRY OF THE LOCAL GOVERNMENT BOARD.

A TOUCHING indication of the esteem and respect in which Dr. Barry, the late senior medical inspector of the Local Government Board, was held is to be found in the fact that a handsome lych-gate has recently been erected to his memory in the village of Down in Kent, where he resided at the time of his sudden and premature death. The memorial in question has been erected by subscriptions from Dr. Barry's colleagues in the medical and other departments of the Local Government Board, as also from many medical officers of health throughout the country. The Yorkshire branch of the Society of Medical Officers of Health, amongst the members of which Dr. Barry spent some years of his official life, have collectively borne testimony by their contributions to the appreciation in which he was held by them. On the inside of the lych-gate is a tablet bearing Dr. Barry's name, together with the following inscription, "Erected by his colleagues and friends in token of their affectionate regard and high esteem of his life's work."

"LIVER-COUGH" AN UNDESCRIBED SYMPTOM OF HEPATOPTOSIS.

IN the *Journal de Médecine Interne* of Oct. 15th, 1898, M. Louis Vène relates the following case. A woman had suffered from cough for eighteen years, which since she came under observation (in 1891) was dry and incessant. Drugs were useless. She was examined by a laryngologist and by a number of physicians, including Professor Simon Duplay. The diagnoses of nervous cough and of hysterical cough were made. She happened to break her clavicle and a bandage was applied for a month which compressed the thorax and upper abdomen. During this period the cough was never heard, which was attributed to preoccupation. M. Vène's attention was attracted to a peculiar symptom—the patient never coughed at night. She said, "I sleep very little, perhaps two or three hours a night; but whether I sleep or not I never cough lying down whatever be my position in the bed." Examination showed that the liver extended to the level of the umbilicus in the right hypochondriac region. Hepatic dulness began at a lower level in the upright than in the recumbent posture—at the seventh rib. The thorax was compressed with a flannel bandage extending from the nipples to the umbilicus. The effect was remarkable. The patient had not a single fit of coughing. This result was maintained by bandaging from the

Digitized by Google

pubes to the nipples with rigid material—cotton or flannel—but corsets and complicated elastic belts proved useless. In none of the various observations on hepatoptosis is cough mentioned as an important symptom. But since Hippocrates "liver-cough" has been known, and, curiously, in 1831, when hepatoptosis was unknown, J. B. de Larroque, physician to the Necker Hospital, in a work on Certain Abdominal Diseases which Simulate, Provoke, and Maintain Diseases of the Chest, distinguishes "liver-cough" due to hepatitis and "liver-cough" coming on in the standing position caused by the weight of the organ. As to the manner of production M. Vène suggests that as the liver is (according to Faure) suspended from the vena cava, which is connected with the diaphragm, excitation of the latter produces the cough. He concludes that before making a diagnosis of hysterical cough the absence of any pathological reflex from the abdominal organs in connexion with the diaphragm, and particularly the liver, should be ascertained.

THE ETIOLOGY OF PUERPERAL FEVER.

THE question of the etiology of puerperal fever must always be a matter of special interest to all engaged in midwifery practice. In 1880 Pasteur first demonstrated the presence of streptococci in a case of puerperal infection, and for a long time it was thought that the streptococcus pyogenes or the products of its growth were the important agents in the causation of puerperal septicæmia. The further researches, however, of Brieger in 1888 and of von Franqué and Krönig in 1893 showed that puerperal fever might be caused not only by streptococci but also by staphylococci, colon bacilli, and gonococci. In the September number of the *American Journal of Obstetrics* Dr. Whitridge Williams records the results of the bacteriological examination of 40 cases of fever in the puerperium. In 22 instances pathogenic organisms were found—viz., the streptococcus in 8, the staphylococcus in 3, the colon bacillus in 6, the gonococcus in 2, the typhoid bacillus and the diphtheria bacillus in 1 each, and in 1 case the bacillus aerogenes capsulatus (gas bacillus) associated with the streptococcus. In 10 of the cases the usual pathogenic organisms were absent, but non-pathogenic bacteria were found, while in 11 cases where there was a more or less marked elevation of temperature the bacterial examination was entirely negative. In the cases where pathogenic organisms were absent it is uncertain what part the bacteria found played in the production of the symptoms, and it is quite possible that their presence may have been a mere coincidence. In the group of cases where negative results were obtained the temperature was no doubt due in some to auto-intoxication from the bowel, as shown by the results of purgation, and in others to mammary disturbances, while in a few no cause could be discovered. It is a well-known clinical fact that many cases of fever in the puerperium readily yield to brisk purgation, and the proof afforded by Dr. Williams's bacteriological examinations that in such cases the temperature is not due to septic infection from the uterus is of the utmost importance. With the fuller knowledge we now have as to the presence of pathogenic organisms in the uterus in cases of puerperal fever the question of what organisms are usually found in the vagina has a renewed interest. In the October number of the same journal Dr. Williams publishes a further paper upon the Bacteria of the Vagina based upon the bacteriological examination of the vaginal secretions of 92 pregnant women. The paper contains a full summary of all the work done upon the subject up to the present time, and Dr. Williams's results fully confirm the important results obtained by Krönig. We cannot do more than quote some of the conclusions arrived at by Dr. Williams although the whole paper will well repay perusal. They are as follows: "The vaginal secretion of pregnant women does not contain the usual pyogenic cocci. As the vagina does not contain pyogenic cocci auto-infection with them is impossible. It is possible, but not yet demonstrated, that in very rare cases the vagina may contain bacteria which may give rise to sapræmia and putrefactive endometritis by auto-infection. Death from puerperal infection is always due to infection from without and is usually due to neglect of aseptic precautions by physician or nurse." The vexed question of auto-infection cannot be regarded as completely settled, but the results of Dr. Williams's examinations enable him to assert positively that the usual forms of puerperal infection are not due to auto-infection, and although it is not impossible for this variety of infection to occur so far it has not been demonstrated. We shall not go far wrong, therefore, if in our midwifery practice we regard the vagina of a healthy woman as free from all such organisms as usually produce puerperal fever and if we remember Dr. Williams's conclusion that death from puerperal infection is always due to infection from without.

FATAL MISREADING OF A PRESCRIPTION BY A NURSE.

A PATIENT suffering from typhoid fever in the Tolworth Isolation Hospital has died from the effects of an overdose of laudanum given by the nurse in mistake. A card for the guidance of nurses was placed at the patient's bedside. On this was written by the medical officer the order for the patient to have an injection of half a drachm of laudanum. The matron directed the nurse to give this. Instead of half a drachm she gave half an ounce. The patient became insensible and died the next day. The nurse admitted at the inquest, held at Kingston-on-Thames, that she had misread the prescription. The jury found that the deceased died from an overdose of opium and expressed an opinion that greater care should be exercised with regard to poisonous drugs.

THE RIGHTS OF CHILDREN IN INDIA AND THE COLONIES.

IT is a regrettable fact that it is still true to a much greater extent than there is any justification for, and in spite of an advanced and Christian civilisation, that the weakest goes to the wall. Illustrations of this fact could be multiplied, but it will be sufficient to quote one of the most obvious. It consists in the cruelty, deliberate and regardless, to which very many children are subjected. With the efforts put forth by the National Society for the Prevention of Cruelty to Children all our readers are familiar. It is to be remembered, however, that that society has hitherto been a national one in the purely insular sense. Even so it has been most useful. We now learn with satisfaction that there is a prospect that other lands than our own will witness the rise of agencies identical with it in their purpose as they are one with it in their justification. A society has recently been formed in Calcutta for the protection of ill-used Indian children and the terms of its constitution are now under discussion in the daily press of India. It has been objected that this new organisation has been established in an exclusively Christian and even sectarian form. While sympathising with the implied ideal we cannot but think that it represents in this instance an error in principle and in policy. The practice of humanity, it should be remembered, is not exclusively Christian, though it has undoubtedly found its best advocacy and its highest development where Christian principles have been allowed to operate. No doubt the present difficulty will be judiciously settled so

Digitized by Google

as to enlist the cordial coöperation of all sorts and conditions of those resident in India, and thus to ensure the more effectual prevention of cruelty in that country. It is of equally happy omen that steps have been lately taken to organise the work of prevention of cruelty to children in Australia and other colonies. The methods pursued by the National Society for the Prevention of Cruelty to Children at home are such that no reasonable objection can be taken to them. Repressive though they must be they are no less powerfully educative, and numerous instances might be quoted in which with a minimum of friction a veritable reformation has been wrought by their means in the treatment of children by their guardians. We regard those methods indeed as representing a species of sanitary procedure in the realm of morals, and we therefore naturally desire for them the widest possible extension.

CYCLONE NEUROSES AND PSYCHOSES.

ST. LOUIS was visited in May, 1896, by a severe cyclone followed by slighter storms. Dr. Bremer some months later read before the St. Louis Medical Society a paper dealing with the nervous effects produced by this series of storms, and an abstract of this appears in a recent number of the *Neurologisches Centralblatt*. Among the most common effects were so-called hysterical and neurasthenic conditions induced in persons who were previously of a neurotic temperament. Hysterical monoplegia, aphasia, and aphonia were among the most common sequels and, on the other hand, there was not infrequently a transitory improvement in the condition of patients who were chronically hysterical. A true "cyclonophobia" was also of not uncommon occurrence and, indeed, everyone was taken with a kind of panic. One case of epilepsy was seen, apparently induced at this time, and malaria was more common than usual, as also was diarrhœa—a state of things considered to be analogous to the alleged connexion between earthquakes and epidemics. In some women the hair became dry and fell out; many people went about as if in a dream, and amongst the healthy there were several who confessed that for weeks and even for months they continued to dream of cyclones. The lower animals, also, especially fowls, dogs, and horses, showed the greatest fear in any subsequent storm. Finally, the interesting question is propounded—What deleterious influence is the cyclone likely to have upon the children born just after it—will there be "cyclone children" as there were the well-known "enfants de siège" in Paris after 1870?

DEATH AFTER MERCURIAL INUNCTION.

THE medical officer in charge of a large asylum—or workhouse as we should term it—in Belgium has recently been compelled to make his appearance in the law courts in a very unpleasant manner. Some months ago he instituted a kind of routine treatment on the admission of all infirm inmates in order to free them from vermin with which they were usually found to be swarming. This treatment consisted in the inunction of a compound of two parts of strong mercurial ointment with three parts of vaseline, followed an hour later by a bath. The average quantity of ointment used was a trifle more than a drachm. The number of patients subjected to this process was 630. Of these 30 showed signs of mercurial stomatitis, 17 of them being obliged to remain in their wards; 3 of these last had to be taken into the infirmary, 1 of whom, an old man, aged sixty-seven years, died a month later. A necropsy was made by the official medical officer attached to the courts and he gave it as his opinion that the mercurial inunction was responsible for the death. In consequence of this report the asylum medical officer was charged with the manslaughter of 1 inmate and with having injured 15 of the others. Several medical men gave evidence that in their opinion the treatment was proper. The court found that "it was not proved that the death was due to mercurial poisoning as it did not take place for a month after the inunction and there had been periods of improvement, and that though the ointment might have caused the stomatitis, this became 'ulcero-gangrenous,' assuming a serious and unexpected character in consequence of organic conditions which induced special morbid phenomena independent of the original cause." A fine of 15 francs was, however, imposed as the court considered that such heroic measures were not suited to all persons and that such a strong preparation should not have been ordered indiscriminately or without a medical examination of each person. This judgment when brought before the Court of Appeal was not sustained and the defendant was finally acquitted. Regarding the contention that he ought personally to have examined the inmates on admission it is stated that he was the sole medical man in charge of the 4000 inmates, that the infirmary always contained from 100 to 200 patients, and that from 50 to 100 consultations had to be given daily to those not in the infirmary, added to which the sole medical charge of the 125 officials and their families, some of whom resided at a considerable distance, devolved upon him, so that it would have been absolutely impossible for him to see and examine all the poor old vagrants and others who might be admitted. The moral of the whole case surely is that workhouses in Belgium require a larger number of medical officers.

THE REMOVAL OF TATTOO MARKS.

IN the *Archives de Médecine Navale* for October there is an instructive article by Dr. Félix Brunet, a junior surgeon of the French navy, on *Détatouage*, or the art of removing pictorial designs and inscriptions from beneath the outer skin. Soldiers and sailors — the latter especially — are notoriously fond of this species of adornment, but men at best are but fickle creatures and with advancing years many among them become anxious to be relieved of the too persistent records which they then no longer look upon as ornamental. As Dr. Brunet says, there are few naval medical officers who have not been asked by patients to remove tattoo marks, but unfortunately when their services are thus required they are obliged to depend upon their own resources, as little or no information is afforded by the text-books. It is true that an immense number of methods have been recommended both in ancient and in modern times, but all are more or less inefficient, while many of them are barbarous. Tattooing varies so considerably as to site, extent, and depth that no single method, however elastic, can possibly answer in all cases. Dr. Brunet enters into an elaborate historical survey of his subject, exhibiting a vast amount of erudition. Among other stories he tells once more how Bernadotte died rather than lay bare his arm for phlebotomy. In his salad days Napoleon's famous general had been an ardent Republican, and had he consented to the uncovering of the limb an elaborate design attesting to his unalterable devotion towards the Republic One and Indivisible would have come to light. In conclusion Dr. Brunet formulates his procedure as follows. "The empirical means proposed for the removal of tattoo marks being either inefficacious or dangerous, while the scientific expedient of re-pricking with various caustics is insufficient, we propose a method, more complicated but surer, and separable into the following stages: (*a*) delimitation of site to be operated on by diachylon plaster, anæsthesia by cocaine; (*b*) vesication by ammonia (*c*) removal of epidermis, free rubbing of exposed design by nitrate of silver

Digitized by Google

pencil; (*d*) after five minutes salt or boricated water dressing, to be renewed the next day, when also the diachylon may be removed; (*e*) cicatrisation under a powder formed of equal parts of iodoform, red bark, charcoal, and salicylate of bismuth. This method is not applicable to all cases. Sometimes, notably in tattooing of the face, dissection is the best treatment. When a very large design is in question it can be dealt with piece-meal." The method would probably be drastic, but whether its author is quite consistent in reflecting upon the barbarity of other processes while recommending his own is open to question.

TUBERCULOUS PERFORATION OF THE SOFT PALATE.

AT the meeting of the Société Médicale des Hôpitaux on Oct. 21st, 1898, Dr. Du Castel read the following case. A man, aged forty-two years, who had been very vigorous, lost flesh considerably. He entered hospital for a painful condition of the throat which almost completely prevented him from taking food. There was an oval perforation of the soft palate, in the middle line, measuring 6 mm. by 4 mm. At first sight it appeared to be syphilitic, but neither history nor examination of the patient revealed anything to support this view. Near the last right upper molar tooth and extending some distance on the palate was an irregular ulcer with granular surface and a yellowish-grey and sanious coating. At its circumference were numerous little yellow granulations presenting all the appearances of miliary tuberculosis of the mouth. At the left border of the perforation was a small granular ulcer with a pultaceous coating exactly resembling that on the former ulcer. Near the latter were three miliary granulations with tuberculous characteristics. The patient was manifestly tuberculous; he had pulmonary cavities, profuse expectoration, night sweats, and diarrhœa. He died some days after admission. The necropsy showed diffuse tuberculosis of both lungs. The nasal mucous membrane near the perforation was ulcerated and papillomatous. Numerous tubercle bacilli were found at the margins of the ulcer. Tuberculous perforation of the soft palate is very rare. M. Talamon published a case in the *Journal de Médecine Moderne* of Sept. 2nd, 1893, and declared that he could not find another in medical literature. M. Talamon's patient, unlike Dr. Du Castel's and the majority of patients with tuberculosis of the mouth, showed no sign of pulmonary tuberculosis and had a cough only a short time. When first seen he had had for several days sharp pains in the throat. There were dusky redness of the posterior part of the soft palate, uvula, pharynx, and tonsils, and irregular ulceration of the left tonsil. Near the latter on the soft palate were three yellow points, presenting all the appearances of tuberculous granulations. They enlarged, coalesced, and ulcerated. On the eighth day the soft palate was perforated. The bacillus tuberculosis could not be found. The patient was treated with cantharidate injections and applications of lactic acid, under which the ulcers almost healed and the perforation became almost obliterated. He then left the hospital.

ON Dec. 6th the meeting of the Pathological Society of London will be devoted to the exhibition and discussion of tumours and other morbid lesions of the pineal body. About eight specimens will, as far as is known at present, be available for the meeting, but any members who are willing to exhibit or read communications on the subject are requested to communicate with the junior secretary, Pathological Society, 20, Hanover-square, W.

THE Indian Government have asked for ten more medical men to serve temporarily on plague or general duty in Madras. Of these, four have already been appointed. Volunteers who may be ready to start for India at two or three days' notice are invited to send their names to the Revenue Secretary, India Office, Whitehall. Candidates must be under forty years of age. Other information may be obtained on application.

SIR JOSEPH FAYRER will soon leave London for a short space of time, but in view of previous incorrect rumours we take this opportunity of stating that his visit will be a short and temporary one. As readers of THE LANCET know it is not our habit to chronicle the movements of medical men, but as a report of Sir Joseph Fayrer's retirement from practice has been widely circulated we consider it fair to contradict it.

AS announced by Sir William Turner the 20,000 copies of the British Pharmacopœia originally printed have already passed into circulation and a reprint has been ordered. We are informed that the opportunity has been taken of indicating a few manifest errors and misprints. A slip containing these corrections may be obtained gratis from the publishers, Messrs. Spottiswoode and Co., Gracechurch-street, E.C.

THE London University Commission appointed under the University of London Act, 1898, has commenced its sittings. The Commissioners are Lord Davey (Chairman), the Bishop of London, Sir Owen Roberts, Sir William Roberts, Professor Michael Foster, Professor Jebb, and Mr. E. H. Busk. The Secretary is Mr. Bailey Saunders.

ON Monday, Nov. 28th, at the Camera Club, Charing Cross-road, Major Beevor, R.A.M.C., will deliver an address on the Use of the X Rays on the Battlefield in the late Operations on the Indian Frontier.

WE are glad to be able to state that there is not the slightest foundation for the rumour that Dr. Hale White contemplates resigning his post of physician to Guy's Hospital.

THE PRESENT STATE OF UNIVERSITY EDUCATION IN GERMANY.

THE November number of the *Nineteenth Century* contains an able and important article upon Recent Progress in German Universities. The writer points out how the events of the last two or three decades have tended to consolidate Germany and to give pre-eminence to Berlin. "Berlin has become a *Welthauptstadt*, a capital among the capitals of the world, conscious of her strength and fully capable of using it. Between the overgrown barracks, set in a plain, and the sovereign city of Imperial Germany, there lie the two great eras which have succeeded the victory over France—the Bismarckian era of union and the era of expansion under the Emperor William II. Both have tended to the aggrandisement of Berlin. The stream of creative invention has turned aside from the minor kingdoms and duchies, and the long line of princes who made of their provincial courts imperial seats of culture is gradually coming to an end." In other words, centralisation, so long the note of French culture, is now to have its turn in Germany, where in the past Weimar has divided intellectual honours with Berlin, Leipzig with Frankfurt, Dresden with Munich. We are spectators of a great secular movement which may be for good or for evil but which seems irresistible. The consequences of this movement must be far-reaching and

Digitized by Google

important. "The young German of to-day," proceeds the writer in question, "has to be educated in quite different duties and ambitions from those which sufficed for the young Prussian, Saxon, Bavarian, or Westphalian whom Matthew Arnold visited thirty years ago. His mental equipment must comprise those signs of union and expansion under which his country has developed. It is not enough to build engines in Dortmund, to worship Goethe in Weimar, to paint pictures in Munich, to tread grapes on the Rhine. The German eagle has planted his talons deep in the united Fatherland, and we are taught that on his wings is commerce and in his flight is peace." The new conception presented to the youth of Germany and to their instructors in culture is that of an epoch of scientific progress, industrial development, and colonial expansion, directed, controlled, and protected by the vigilant eye of the Kaiser. It will be admitted, at all events, that this is a much higher and nobler conception than that of a pure military *régime* of drill, barracks, and conquest.

This new conception of the object of life and the probable trend of national development is powerfully affecting university education in Germany. New subjects are being introduced into the curriculum, old subjects are being appraised by new standards, technical education and economical questions are receiving a great impetus. There are now, it would appear, no less than 4000 technical chemists in Germany who have enjoyed a university education. Thirty years ago the professors in the Berlin University devoted thirteen hours a week to the study of political economy. This amount of time is now more than doubled. The range of this subject has been extended and now includes such questions as labour rights, currency problems, social protective legislation, economic meaning of machinery, and so forth. The result is, on the one hand, to spread abroad juster conceptions of economic and industrial questions, and, on the other hand, to put into the hands of the Socialist party powerful weapons which they have been quick enough to use.

It is interesting to note what has been the German development of the idea of university extension, inasmuch as opinion in this country is somewhat divided with regard to the utility of the movement. It would appear that at various centres *Volkshochschulkursen*—popular university courses—were established and that their fortunes were various. In most cases the universities favoured the movement, while the State was hostile. At Munich Professor Brentano and some of his colleagues in the university threw themselves into the work, but the Bavarian Government refused to recognise the movement, and withheld the loan of the university lecture rooms with their various fittings and appliances. In spite of this opposition no less than 1500 persons, of whom about 1000 were males, attended the lectures in one session. Artisans and shopkeepers made up more than half the roll, and followed the instruction with regularity and intelligence. In Berlin the university senate has always refused its adhesion to university extension. It would appear that the movement is on the whole languishing in Germany from want of funds. The State is generally more or less hostile and private benevolence has not been conspicuous. The official hostility to the university extension movement seems to be chiefly influenced by a dread of the further growth of Socialism among the masses of the people.

The writer in the *Nineteenth Century* gives much interesting information regarding the status and functions of the *privat-docent*—that peculiar feature of German university life. He quotes Matthew Arnold to the effect that the *privat-docent* is "peculiar to Germany and is the great source of vigour and renovation to her superior instruction. ..... The *privat-docent* is an assistant to the professoriate and his lectures count as professors' lectures to those who attend them. His appointment is this wise. A distinguished student applies to be made *privat-docent* in a faculty. He produces certain certificates and performs certain exercises before two delegates named by the faculty and this is called his *habilitation*. If he passes the faculty names him *privat-docent*. ..... He is then free to lecture on any of the subjects proper to his faculty. He is on his probation, he receives no salary whatever, and depends entirely on his lectures; he has, therefore, every motive to exert himself." There can be little doubt that this is an admirable system, but it has grown up naturally in Germany and it is a serious question whether it could be transplanted to this country. It must be remembered that the *privat-docenten*, although often men of the highest culture and attainments, are content to work on year after year upon the scantiest incomes in the hope of future promotion. The comparative simplicity of manners in Germany, and let us in justice add the widespread love of knowledge for its own sake which exists in that country, make such a system possible. It is doubtful if many Englishmen of first-class attainments would work on for years upon the income of a clerk or an engine-driver.

The "modern" side of education is, we are informed, making great strides in Germany, and the technical colleges have kept pace with this development. A "Commercial College" was opened at Leipsic on April 25th of this year, and its aims and programme are understood to be in consonance with the Kaiser's views regarding the industrial development of the Empire. "The college aims at training a generation of business men, intellectually and socially as fully equipped as any 'Herr Doctor' of the conventional university course. It is not only, it is not primarily, designed for the benefit of trade itself. Indirectly, no doubt, the Empire will gain when its commercial classes and consular profession are recruited by men of university stamp. But its chief aim is the ideal one of benefiting the recruits themselves."

A VISIT TO THE SANATORIUM FOR CONSUMPTIVES AT NORDRACH.

BY THOMAS GLOVER LYON, M.A., M.D. CANTAB.,
PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK;
AND
CHARLES LAMPLOUGH, M.D. BRUX.,
LATE RESIDENT MEDICAL OFFICER TO THE HOSPITAL.

NORDRACH is a village situated about 1400 ft. above the level of the sea, some 20 miles south of Baden-Baden, in a valley of great natural beauty running up in a winding fashion towards the north-east amongst the mountains of the Black Forest. It is best reached by a drive of nine miles from Biberach-Zell. The rainfall is rather above the average, but there is plenty of bright sunshine. The atmosphere, remarkably free from dust, is at once genial and invigorating. Even in winter the patients can sit about in the open air with comfort. There are no mists here and catarrh is unknown. The valley is far away from all public entertainments; there is nothing to distract the patients from following the somewhat rigorous treatment. The means of communication with the rest of the world are under control and the right to open parcels coming to patients is reserved. The village inn was secured by Dr. Walther at the foundation of the colony, so that it is impossible for patients to break the dietary rules laid down for them.

The four pavilions, containing between 40 and 50 beds, present no special features except that arrangements are made for a complete system of airing, washing, and sunning of the rooms and corridors. Ledges where dust might collect are avoided. The bedrooms all look towards the south-west and the windows are of the "French" pattern

Digitized by Google

with a broad flap at the top opening outwards and upwards, so that this window space can be utilised for ventilation even during a heavy rainstorm. Each bedroom contains a shower-bath. There is a large dining-room, amply provided with windows, which are rarely closed, even in winter. There are no specially constructed shelters; protection from the weather is provided by the pavilions and places protected by nature. Attached to the sanatorium are a laundry, where all articles are steam-cleaned, a steam disinfector, an ice-house for keeping provisions, and an electric-lighting plant. Cows are kept for the use of the sanatorium. There are paths marked out as to distance and gradient running on the hillside amongst the trees.

The nursing staff has been specially trained at Nordrach. It is found here, as at other sanatoria and hospitals for phthisis, that women who have not gone through the exciting work of surgical and acute medical wards are more easily induced to take interest in phthisical patients and to carry out details of treatment essential in their management.

Patients are under strict medical supervision, being visited in their bedrooms three times a day, and the resident physician takes his meals with those patients who are allowed to dine "in hall." The patients are weighed every week and their temperatures taken four times daily. The only object recognised in the treatment is the cure of the disease; all other considerations must give way to this. Any deviation on the part of the patients from the daily routine prescribed is certain to come to the cognisance of the medical superintendent. However, the marked improvement noticed by the patients themselves soon reconciles them to the rather trying *régime;* here the good offices of the senior patients are found to be of great service.

As some misunderstanding exists about the matter a sketch of the method of treating phthisical patients at Nordrach, gathered from Dr. Otto Walther, who has carried out this system for the past nine years, may not be without interest. This should be prefaced by saying that no treatment for "hardening" patients is used, as at some sanatoria, anything of the sort being found quite unnecessary. The treatment proper may be placed under six headings: (1) sanatorial and self-discipline; (2) medical supervision; (3) fresh air; (4) regulated and induced feeding; (5) regulated exercises and rest; and (6) limited recreation.

1. *Sanatorial and self-discipline.*—These are very important points in the Nordrach treatment. It is here that the personality of the medical officer plays a great part. The details will appear later, but, generally speaking, the discipline referred to consists in suppressing habits which have aggravated or caused the disease and in cheerful submission to the line of treatment calculated to restore the patient and ensure non-recurrence of the disease after leaving the sanatorium. Seclusion from the busy world and freedom from the visits of friends materially assist in the treatment. If it is impossible to get to public entertainments the desire to go to them is easily suppressed. The disturbing influence of the visits of friends is well known in every hospital, but in such a colony as Nordrach they are more than usually harmful. They engender discontent and so depress the patients. People suffering from phthisis do not want "sympathy" except when *in extremis;* they like someone to make light of their symptoms and give them encouragement.

2. *Medical supervision.*—All patients are seen three times a day, some even more frequently. It is thought that one medical officer cannot with advantage look after more than from forty to fifty patients. Medicine is rarely given; tuberculin, antiseptics, and antipyretics have been tried in cases where the ordinary open-air treatment has failed, but the results have always been disappointing. The two drugs found most useful have been salicylate of soda and iodine, of which mention will be made later. A modified form of Dettweiller's flask is carried by each patient for use out-of-doors, spitting on the roads being prohibited; cups containing water are used indoors.

3. *Fresh air.*—This is the cardinal factor in the treatment. Patients are always in the fresh air—they sleep, eat, rest, and exercise themselves in the open. The windows are never closed whilst the patients are indoors; in very cold weather the patients shut them as they go out, so that they may return to warm rooms. It is surprising to hear how soon patients become reconciled to all this. In fact, any attempt to close windows is soon resented, for the patients immediately feel the depressing influence of vitiated air, and the necessity for a continual supply of fresh air remains with them after leaving the sanatorium. The genial climate of Nordrach is doubtless of great importance in this part of the treatment; not only must it be of service in making easy the assumption of open-air habits, but the absence of the depressing effects of many climates at certain times of the year must claim a considerable share in the result attained.

4. *Regulated and induced feeding.*—Except in severe cases, when the abundant use of milk is obligatory, there is nothing very special in the dietary. Food is taken regularly three times a day with nothing to eat or drink between whiles. Patients are induced to take as much as possible, especially of fatty food, and in most cases rather more than the natural appetite dictates. A little wine or beer with the food is allowed if desired. Encouragement to self-discipline plays an important part in this connexion, and a reference to the change of weight also is found to have a marked effect on the powers of deglutition. In some cases persuasion to take food is carried to an extent justified only by the surprising results obtained. It is considered that the vomiting and anorexia frequent in cases of phthisis are caused either in a reflex manner from irritation of the lungs or by the action of the tuberculous poison on the nerve-endings in the stomach itself. It is found that with perseverance, even after several vomitings, food is usually retained. It has been observed here and elsewhere that this condition of stomach is sometimes relieved by administration of tincture of iodine in 3 minim doses or so, or of about 10 grains of salicylate of soda, the ordinary stomachic drugs being inert. It should be remembered in this connexion that at Nordrach catarrh is unknown. Exaggerated ideas as to the system of feeding have got abroad owing probably to the use of the term "forced feeding." Dr. Walther suggested "induced feeding" as more accurately descriptive of his method. It is more by the example set them by senior patients that new arrivals are induced to partake of large meals than by any method of forcing employed by the physician. This system of calling upon the assimilating powers of the patient to fight a wasting disease must be a prominent factor in producing the astonishing results obtained.

5. *Regulated exercises and rest.*—These means of increasing vitality are used with the greatest care and vigilance. As long as any fever is present the patient is kept strictly in bed, no one except the nurse is allowed to enter his room, and she converses with her patient as little as possible. A week after the temperature has not risen above 100° F. or fallen below 98° walks regulated to the case are prescribed. The temperature is taken immediately after every walk, and if there is a rise above 100° a reduction of distance or gradient, or even return to bed, is ordered. The temperature is always taken in the rectum, for temporary rises due to over-exertion often disappear before they could be registered in the mouth or axilla. After each walk and before meals an hour's absolute rest is enforced. This rest must be taken alone, even conversation being forbidden.

6. *Limited recreation.*—Exciting amusements of all kinds and such as necessitate crowded rooms are prohibited, but recreation of a quiet nature is allowed. Formal entertainments are never given, but a piano is provided for the patients' use.

It will be seen from the above that the method of treating phthisis at Nordrach does not consist in pushing one or two supposed specific remedies, but in carefully employing to the utmost, under specially favourable conditions, means well known to assist the patient to battle with the disease. It is very important to bear this in mind at the present moment, when there is too great a tendency to rely upon "fresh air" alone as a specific for phthisis.

As to the results of the treatment, a cure is claimed if the temperature remains normal, if the patient regains his normal weight and strength, if he is able to follow his occupation with comparative comfort, and if he maintains this condition for some years. In some of these cases bacilli may be found in the sputum, but the disease is assumed to be arrested by fibrous tissue from further invading the lungs. Patients are encouraged to send reports of their condition to the resident physician after leaving the sanatorium. It is found that unless the *régime* inculcated at Nordrach can be continued to a large extent after the patient returns home relapses are very common, so that in the case of poor patients living in towns all the benefits produced by the treatment are often found to vanish in a very short time. It has been asserted by many that the cure is more permanent when

Digitized by Google

the patient is treated in his native country, but the evidence brought forward in support of this statement is as yet, we think, insufficient. The most obvious course to pursue is to put all patients as far as possible under the most favourable conditions for recovery. The result of the Nordrach treatment on the general appearance of the patients is very striking. It is difficult to believe that they are suffering from pulmonary tuberculosis. The anxious look and slow, constrained movements of the phthisical patient are wholly wanting. Those who can get about are bronzed and healthy-looking, with a cheerful, confident expression of face and brisk, free movements. More than 50 per cent. of the patients are English, the rest are chiefly Germans and there are a very few French people. Dr. Walther did not quote statistics, which are always difficult to apply correctly, but gave us the following general account of the result of his treatment. He refuses no sufferer from phthisis admission if there is room in his establishment, so that patients in all stages come under his treatment. Some in spite of every care continue to get worse, but these cases are quite exceptional—they appear naturally unable to combat the disease. Of the rest early cases do the best and usually go away cured. Respecting the seriousness of any case physical signs are not taken as the guide, but rather the effect of treatment on the general condition during the first few weeks after admission, for it has been found that patients presenting signs of advanced disease in both lungs have made a very good recovery even when on arrival they were extremely emaciated and suffering from the grave symptoms which accompany such a condition.

What cases, it may be asked, should be sent to Nordrach or to similar institutions? As the success of the treatment at these sanatoria depends, within limits, upon the resisting powers of the patient rather than upon the exact stage of the disease, it is advisable before sending a patient abroad to watch the effect of treatment as nearly as possible like that employed by Dr. Walther, either under private supervision or at a sanatorium. If no definite improvement take place the case is not likely to derive much benefit from the treatment at Nordrach and removal from England should not be urged. Some, especially the early cases, will recover under treatment at home. Others after improving up to a point will remain stationary for a time and then if more effectual measures are not taken will slowly sink. These cases imperatively call for treatment in a more favourable climate and unless financial or other reasons render it impossible they should be sent without delay to Nordrach or a similar establishment. Of course, if there is no reason to the contrary it would be best to send all except the hopeless cases to a place like Nordrach as early as possible. Another question naturally arises, How far could these methods be pursued with advantage in England? A careful consideration of the matter must end in the conclusion that our climate is an insuperable bar to the carrying out of such treatment in its greatest efficiency. Recent reports show that much can be done by establishing well-organised sanatoria in favourable situations, but these cannot be expected to produce quite the results obtained in the Black Forest. The impression left upon the mind by a visit to Nordrach is most encouraging. However sceptical one may be one comes away with the conviction that means are within our reach to cure in most cases a disease which a short time ago was regarded as almost hopeless.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE LANCET of Nov. 19th contained a brief note on the thirty-fifth sitting of the Royal Commissioners which was held on Nov. 15th. At the commencement of the proceedings Mr. PEMBER asked the chairman to allow him to put a question to Mr. Bryan, engineer of the East London Waterworks Company, with regard to a complaint which had been sent to the chairman as to the water-supply in Green-street, Upton Park. Mr. BRYAN explained that the deficiency in the supply was due to a defect in the ball-valve in the house of the customer who had complained. The witness, in answer to further questions, said that according to the returns of the Registrar-General there was no increase of typhoid fever in the metropolitan part of the East London Company's district.

The CHAIRMAN said that he had received a communication from the Board of Guardians of the West Ham Union saying that they had an unprecedented number of cases of typhoid fever, which they believed was due to the insufficient supply of water during the past four months. The witness said that he had no statistics with regard to the borough of West Ham, but that lately the mortality there had been nearly as low as that of Brighton, and according to the death-rate of the past six or seven months it might become a "new sanatorium almost."

Mr. BALFOUR BROWNE pointed out that according to the figures which the witness had given on the previous day the supply in September, 1897, was 42,128,000 gallons, and in September, 1898, 24,785,000 gallons, and that there was therefore a deficit which the company had to make good from elsewhere of 17,343,000 gallons, and that this amounted to no less than 41 per cent. of the total supply which should have been given. He pointed out also that in October, 1898, the supply as given by the witness was 41,752,000 gallons daily, and that the supply from the sources of the company was 23,112,000 gallons, and that this left a deficit of 18,640,000 gallons, or 44½ per cent. of the total quantity which should have been supplied and would have been necessary had there been a constant supply.

In answer to the CHAIRMAN Mr. BALFOUR BROWNE pointed out that the 41 per cent. and 44 per cent. were 41 and 44 per cent. respectively given on the average supply of 1897 during those two months.

In answer to Lord ROBERT CECIL, who appeared on behalf of the Hertfordshire County Council, the witness said that the company had six wells now working and that they were situated respectively at Lee Bridge, Walthamstow, Chingford, and Waltham Abbey, and that wells were under construction at Ponder's End, Rammey Marsh, Walthamstow, and Old Ford. At Waltham Abbey when pumping ceased the water overflowed; at Chingford, the next well, when pumping ceased the water rose to within about 12 ft. or 14 ft. of the surface. At Walthamstow the water level was about 30 ft from the surface and at Lee Bridge about the same distance. As, however, pumping had been going on continuously for many months the witness could not say what the present rest level would be. They were extending the underground channels at Walthamstow and the water was therefore kept constantly pumped out.

In answer to the CHAIRMAN the witness said that during the late period of drought the water rose in the wells when pumping ceased. They had had to stop on two occasions at Chingford in order to pack the pumps. They had also found it necessary to stop at Walthamstow and at Lee Bridge. In every case the water had risen to a height of perhaps from 100 ft. to 170 ft. above the pumps. This happened during the last fortnight.

Lord ROBERT CECIL examined the witness with regard to the flow of water in the Lee. He called attention to a paragraph in the report of the Balfour Commission to the effect that "the supply of the New River Company from the River Lee is regulated by the River Lee Water Act of 1855, under which a quantity of about 5,400,000 gallons daily is reserved for navigation, and as much as may be necessary in addition to keep up the head of water in each level of the river." The witness said that according to his reading of the Act this amount of 5,400,000 should be reserved for navigation.

In answer to further questions the witness said that of 8,000,000 gallons which were discharged over Fielde's Weir the company in September took 7,100,000 gallons and that therefore only about 1,000,000 gallons were left for navigation purposes. In October the flow was about 15,000,000 gallons daily, of which 10,700,000 gallons were taken by the East London Waterworks Company. It followed, therefore, that the statutory rights conferred for the purpose of navigation by the Act of 1855 were not enforced by the Lee Conservancy. The witness said that the Lee Conservancy did not enforce the provisions of the Act.

Mr. MATHEW WILSON HERVEY, engineer to the West Middlesex Waterworks Company, in answer to the CHAIRMAN, said that during the month of June they pumped 23,124,933 gallons; in July, 23,917,011 gallons; in August, 22,870,405 gallons; in September, 23,504,445 gallons; and in October, 21,372,626 gallons. These quantities were sufficient to supply their district. The quantity of water which they had to spare in June was 1,375,067 gallons per day; in July, 582,989 gallons per day; in August, 1,629,595 gallons per

Digitized by Google

day; in September, 995,555 gallons per day; and in October, 3,127,324 gallons per day. The company had now ample filtering capacity and had just finished four additional acres of filters, which brought their total filtration area up to nineteen acres. They would therefore be able to treat from 33,000,000 to 35,000,000 gallons daily.

In answer to the CHAIRMAN the witness said that at present they would not be able with their present pumping power to supply more than 1,500,000 gallons a day to any other company. The total amount of storage capacity which they possessed at present was 397,500,000 gallons. The witness agreed with the engineers of the other companies that the Battersea scheme would be a good one. He was not prepared to say, however, that each respective company would be likely to require it. The West Middlesex Company had not required such help in the past, and if they maintained their works in their present state of efficiency he did not think that they would require it in the future.

In answer to Mr. DE BOCK PORTER the witness said that the West Middlesex Company had always been in a position to meet the requirements of their district. From time to time it became necessary to extend their works and the company had always been prepared to do so when it was necessary.

In answer to Major-General SCOTT the witness said that at the present time the companies had statutory rights to take 185,500,000 gallons daily from the Thames and there was at the present time a considerable surplus—that is to say, all this water was not required for the supply at present given. The amount actually taken from the Thames was on an average 114,000,000 gallons daily. The margin between 114,000,000 and 185,500,000 was surplus.

Major-General SCOTT suggested that by an arrangement between the companies, by intersale or by some other means, the companies without increasing the statutory limits of their total authorised intakes could provide 15,000,000 gallons of water daily for Battersea.

In answer to Mr. BALFOUR BROWNE the witness said that at present, as far as the West Middlesex Company was concerned, he did not think the Battersea scheme was necessary except as an insurance, but "one never knows what misfortune may befall one."

Mr. RICHARD HACK, chief engineer to the Chelsea Water Company, in reply to the CHAIRMAN, said that they had statutory power to take nearly 10,000,000 gallons of water daily in excess of the amount which they required for their own customers. They were authorised to take 22,000,000 gallons daily, but at the present time they had not sufficient works to filter more than 17,500,000 gallons daily.

In answer to Mr. DE BOCK PORTER the witness said that the largest supply given on any one day was 16,000,000 gallons, which left 1,000,000 gallons which they would be able to spare.

Major-General SCOTT examined the witness at some length with regard to the passage of water from the mains of the Chelsea Company to those of the Southwark and Vauxhall Company. The witness said that in the daytime the pressure in the Chelsea Company's mains was greater than that in the Southwark and Vauxhall Company's mains, but in the night the pressure, he believed, was less. The Chelsea Company could, therefore, only supply water into the mains of the Southwark and Vauxhall Company during part of the day.

In answer to the CHAIRMAN the witness said that they would not be able to supply more than 3,000,000 gallons during any day. The Chelsea Company did not want the intercommunication scheme for themselves, but he thought that it was desirable that intercommunication should be made because it was useful in case of breakdown. Hitherto they had had no trouble in connecting up their own mains in cases of accident.

A question here arose as to the paper called the "Amended Report of Engineers" which had been sent to the Commissioners.

The CHAIRMAN pointed out that the Battersea scheme, or Scheme No. 2 as it was called, had been originally spoken of by Mr. Collins as a scheme of his own. Afterwards a print had been handed to the Chairman through the Secretary, he did not know by whom. The paper had never been proved.

Mr. FREEMAN pointed out that it was not on the notes and the CHAIRMAN said that it never had been put in by anybody.

Mr. PEMBER explained that the companies had sent the amended report "as an official communication from all the companies concerned, and they thought that would probably be enough."

Mr. ERNEST COLLINS was then examined by the CHAIRMAN, who asked: "Is this print Scheme No. 2?" The witness replied that it was.

The CHAIRMAN asked whether it was approved by all the companies. The witness replied that it had been sent in with the knowledge of the chairmen and proceeded to explain its working.

Mr. WILLIAM MORRIS, chief engineer to the Kent Company, said that he generally approved of the Battersea scheme, but he thought it required a little modification in order to give the Kent Company the benefit of it. The point was that the Kent Company would be able as a receiving company to obtain 4,000,000 gallons daily should they require it, whereas the Chelsea Company was to have 10,000,000 and some of the other companies 20,000,000 gallons daily. If it were provided that the Kent Company should if they required it receive the same amount of water as the Chelsea Company it would probably place them on a fair footing.

In answer to the CHAIRMAN the witness said that he did not expect that the Kent Company would require an extra supply of 4,000,000 gallons daily. It was a question of insurance. The CHAIRMAN asked what they wanted to insure against? The witness replied that it was against accident or unforeseen emergency; but in answer to a further question he said that he could not foresee anything beyond accident.

In answer to Major-General SCOTT the witness said that they were pumping from one of the very best reservoirs they could possibly have—that is, from the chalk, that any change taking place would be very gradual, and that they therefore had a very large insurance at present.

In answer to Mr. DE BOCK PORTER the witness said that the drought had affected the Orpington well, the ground elevation of which was 120 ft. above ordnance datum. No other well had been affected.

Mr. JOSEPH FRANCIS, one of the engineers of the New River Company, in reply to the CHAIRMAN, said that he had charge of the wells in the northern part of the New River system. The company had pumped more than usual during the past summer. The witness said that he had not the figures with him but that he would have provided them had he expected to be called. The Chadwell spring had failed this year.

In reply to Sir JOHN DORINGTON, the witness said that the water was delivered into a round basin and a leakage had occurred in that basin which allowed the water to flow out into the surrounding chalk.

In answer to the CHAIRMAN the witness said that the crack in the basin had prevented the water from rising to the usual level.

In answer to Lord ROBERT CECIL the witness said that his reason for believing in the existence of this crack was that the water had never sunk from the basin before; that, he thought, absolutely proved the existence of a fissure.

In reply to further questions from Lord ROBERT CECIL the witness said that they took gaugings of the Chadwell Spring, and in answer to a further question as to whether they had any objection to supplying the gaugings he said he thought that they had.

In answer to the CHAIRMAN the witness said that the Lee had been lower this year than they had ever known it in previous years. The deficiency was due to the higher sources; there was no connexion whatever between pumping from the wells and the deficiency. The effect of pumping from the wells was purely local. The wells were fed by a stream of water passing through the chalk from high ground. In answer to a further question the witness said that the high ground was situated more than a quarter of a mile off. The pumping from the well affected the underground stream on the lower side of their well—that is, in the direction in which the water was going, but beyond a very small range it did not have any effect in the other direction.

Sir ALEXANDER BINNIE, in answer to the CHAIRMAN, said that he had considered the Battersea scheme and that he did not think under existing circumstances that it was necessary. He was more in favour of Sir Henry Knight's scheme.

Mr. BALFOUR BROWNE, on behalf of the London County Council, suggested that he should be heard with regard to

Digitized by Google

the Battersea scheme. He thought the question was more a matter for argument than for evidence.

The CHAIRMAN thought the question was more one for the consideration of evidence than for argument.

THE HEALTH OF THE CITY OF BELFAST FOR 1897.

THOSE who are interested in the question of public health will find in the report just issued for 1897 by Dr. Whitaker, superintendent medical officer of health of the city of Belfast, an amount of material well worthy of perusal. There were 336 deaths from typhoid fever during the year 1897, as compared with 136 in the preceding twelve months; and, as we might expect, during the prevalence of the disease the deaths from diarrhœa were also more numerous than usual. 4813 cases of infectious diseases were reported (the Notification Act came in force on March 1st) and of these 3269 were cases of typhoid fever, the next largest number being 431 cases of scarlet fever. It is curious that the deaths from infectious diseases during the past year were not as numerous as in some of the preceding years, the increased numbers being entirely due to typhoid fever and diarrhœa.

There were 995 deaths from phthisis and 1675 from other diseases of the respiratory organs. The annual death-rate was 23·0 per 1000, while the birth-rate was 33·3, these calculations being based on a population estimated by Dr. Whitaker as 310,000. This population, of course, refers to the old municipal boundary. At the end of the year the suburban districts were added, so that in his next report Dr. Whitaker will deal with a city whose area has increased to 16,503 acres, with a population of 340,000. Coming to the causes of death, of the total number registered (7225) during the year it is appalling to find that 2670 were attributed to phthisis and diseases of the respiratory organs; of these 995 were due to the former and 1675 to the latter cause. This truly terrible loss of life, Dr. Whitaker says, beside which that from zymotic diseases sinks into comparative insignificance, occurs not only in Belfast but is quite as serious in other Irish cities and towns which have more healthy surroundings, a more equable temperature, and less unhealthy industries. Truly, here is ample material for the new crusade against tuberculosis to investigate. The medical officer of health of Belfast thinks that the effect of good sanitary work would be to reduce the death-rate from phthisis. The public in Belfast have clearly not grasped the fact that it is hopeless to eradicate this disease if they will not give up overcrowding and have ventilation and go in for sunshine and fresh air, and also take steps to prevent its spread by getting rid of the bacilli in the expectoration. Phthisis in Belfast causes more than half the number of deaths due to all other chest affections and about one-seventh of the total mortality. There can be no doubt that in Belfast the bad drainage, the damp atmosphere, and the frequent absence of sunshine contribute largely to the prevalence of phthisis, but overcrowding in the various industries and the prevailing ignorance as to the contagiousness of the disease are more important factors; and it is worth remembering in this connexion that it was in Belfast that Dr. Henry Mac Cormac (father of the President of the Royal College of Surgeons of England) long ago taught the enormous importance of fresh air.

With reference to typhoid fever it is deplorable to find Dr. Whitaker stating that while in almost every other town in the United Kingdom the deaths from this cause have been steadily declining in Belfast it is the reverse. He has examined the condition of 2321 houses in Belfast in which the disease occurred and has found that 353 of these had privies and pits with back passages; that 750 had privies and pits without back passages, and the excreta had to be removed through the dwelling house; and that 1218 occurred in the houses which had water-closets. Inasmuch as there are some 65,000 houses in the city, and of these only about 45,000 have water-closets, it is evident that typhoid fever was much more prevalent in the houses with privies than in those of the former class. It is a very noteworthy fact that whilst typhoid fever occurred in 2·7 per cent. of the houses having water-closets the houses with privies had 5·5 per cent. Dr. Whitaker says he agrees with the medical officer of health of St. Helens that the three most patent factors in fostering typhoid fever are defective sewerage and drainage, privy middens, and other filth nuisances, and yet he is puzzled in many cases to account for the disease. He says that in many of the cases the sanitary conditions in and about the houses where the disease prevailed were of a very bad order. On the other hand, he has inspected many well-built, well-sewered, newly-built, and airy houses with good sanitary arrangements in which cases of the disease have occurred, and on strict examination and inquiry he could find no cause for the prevalence of the disease. But surely this proves nothing. For if it be admitted that a disease like typhoid fever prevails in a city with a large working-class population it is easy to understand how one set of individuals who happen to have insanitary dwellings may infect others who live in houses apparently free from any defects. Dr. Whitaker mentions that in the early months of the year, when the number of cases of typhoid fever became numerous, a number of members of the Public Health Committee visited the Stoneyford reservoirs for the water-supply of the city and inspected the adjacent grounds. They found that the ground in the neighbourhood was heavily manured, and in some cases a stream communicating with the works was being contaminated by farm-yard refuse. They also found that there had been three cases of typhoid fever which had occurred about that time in a farmhouse immediately adjoining one of these streams, and although it could not be said positively that the contamination of the water had been the cause of the outbreak in Belfast yet the facts admitted of grave suspicion. It would appear that the disease has not been confined to any district of the city, but it is a curious fact, Dr. Whitaker says, that the two districts of Belfast (Dock and Millfield) which he considers most insanitary are those in which typhoid fever is least prevalent—an observation noted as also applying to other cities, as, for instance, Paris. The worst districts for typhoid fever appear to be Ballymacarrett and the Shankhill. In the former the houses are built on low-lying ground; in the latter they are on a high level with a tenacious clay soil. In both places there is a working-class population.

It will be seen that Dr. Whitaker comes to no definite conclusion as to the cause and prevalence of typhoid fever in Belfast. While he hints that the facts observed at Stoneyford admits of grave suspicion that contamination of the water has been the cause of the outbreak his report proves to the hilt how insanitary a city Belfast is, and explanation is badly wanted to show why it is that such institutions as the gaol and the asylum, situated within the city of Belfast and using the town water, have to such a great extent escaped the disease? We congratulate Dr. Whitaker on his most careful and highly interesting report, and although he has not solved the riddle how it is that typhoid fever is so prevalent in a new city like Belfast he has printed a series of recommendations drawn up by a number of professional gentlemen in Dublin (who investigated the causes of the prevalence of the disease there) which certainly if applied should go far to stamp out typhoid fever, and he has also given ample justification for the series of letters written last year by our Special Sanitary Commissioner. May we in conclusion suggest that a map of Belfast showing the boundaries of registrars' districts would be a most useful addition to Dr. Whitaker's excellent and suggestive report.

BURIAL WITHOUT CERTIFICATES.—At Helston (Cornwall), on Nov. 17th, the sexton of Godolphin Church pleaded guilty to burying on Sept. 24th two bodies of infants (one stillborn, the other having lived nine hours) without certificates. The case was brought forward by the Registrar-General as a warning, but he did not wish to press hardly on defendant. The man was fined 2*s.* 6*d.* and 6*s.* costs.

SCHOOL HYGIENE IN JAPAN.—An order has been issued, says the *Allgemeine Medicinische Central-Zeitung*, by the Japanese Minister of Education that the medical officers attached to the public schools shall not only inspect the schools as heretofore at the beginning and end of the school year but must visit them at least once a month during school hours for the purpose of noting any points of defective sanitation.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Manchester Sanitary District.—The estimated population of Manchester at the middle of 1897 was 536,426, the birth-rate was 32·88, and the death-rate was 22·36 per 1000. For two years in succession the death-rate has been below 23 per 1000 and as there are indications that the 1898 rate will not exceed this figure (which has never been so low for two years following before) Dr. Niven hopes that the efforts of the past few years have not been without their effect on the death-rate. Of the deaths occurring in Manchester during 1897 20 per cent. took place in public institutions. There are always so many matters of interest in Dr. Niven's annual report that it is somewhat difficult to know what to select for notice—so much so, indeed, that it is perhaps almost better to indicate briefly the contents of the volume for the guidance of our readers than to devote space solely to one subject in it. Into the question of school influences Dr. Niven has gone very minutely, and it is interesting to learn that the results of his inquiry clearly support the conclusions of Mr. Shirley Murphy, with which our readers are familiar. Dr. Niven has approached the subject in a fashion which will doubtless commend itself—i.e., he has endeavoured to trace the influence of each school in spreading, or in influencing the spread of, scarlet fever. It is clearly important to study this aspect of the question since it is obvious that in dealing with the district figures as a whole the influence for harm which may have been exerted by two or three schools may be entirely swamped by the absence of such influences in the remainder of the schools in the district. In connexion with the subject of enteric fever Dr. Niven speaks most highly of the value of the blood-serum test which has been carried on during 1897 and he promises us a full and detailed report upon the subject at a future date. Enteric fever manifested considerable infective power in Manchester during the year and in as many as fifty-four cases strong evidence was obtained pointing to personal infection. Outbreaks of this disease occurred in certain institutions under circumstances throwing grave suspicion upon infected closets as the source of the mischief, and valuable records are given illustrative of the manner in which enteric fever may cling to houses once infected with this disease. As regards the prevalence of tubercle in milk imported into Manchester as compared with that drawn from cows in the city itself Professor Delépine has carried on a series of examinations of samples collected at the railway station. Dr. Niven will present a full report on this question later, but he states that the examinations show that the average milk imported from the country is nearly as capable of conveying tuberculosis as is the milk collected from the most diseased cows in the city of Manchester, including even those with obvious tuberculosis of the udder. There has been during 1897 a check put upon the wholesome conversion of back-to-back into through houses owing to the enormous demand there is at the present time in Manchester for all sorts of houses, and the difficulty there is in obtaining unoccupied houses of any description. With a view to relieve this condition of affairs an effort is being made to obtain convenient means of transit for workmen under the Cheap Trains Act, 1883, in order that the central congestion may be relieved and the workmen enjoy better health.

Sunderland Urban District.—Dr. Harold Scurfield has compiled a complete and interesting report upon the health of this district (population 142,107) during 1897. Amongst the 33 great towns Sunderland does not at present occupy a very creditable position, being for 1897 twenty-seventh on the list as regards "fever," seventeenth as regards diarrhœa, and tenth as regards infantile mortality. Dr. Scurfield thinks that the relatively good position of Sunderland in this latter respect is due to the small amount of female factory labour in the district. In reference to the control of measles and whooping-cough arrangements have been made by which the school attendance officers report to the medical officer of health all cases of these diseases which come under their notice, and it is hoped that this method of notification will lead to good results in lowering the fatality-rate of these two diseases. Enteric fever is still abnormally prevalent in Sunderland, and the presence of 11,000 open privy middens is thought to be in large part responsible for this endemicity. It is of interest to read that in streets where the privy middens have been converted into water-closets there has been a considerable reduction in enteric fever incidence. Dr. Scurfield reports that an inspection of the public elementary schools was made during the year under review and that tests were made of the air in the class-rooms both before and after the usual recreation interval. Before the interval the average amount of carbonic acid per 10,000 parts of air was in the Board schools 10·36 and in the denominational schools 13·6; some thirty minutes after the interval in the Board schools 8·9 and in the denominational schools 9·32. The average amount of cubic space per scholar is greater in the Board than in the denominational schools. The investigations showed, amongst other things, that the class-rooms were not always emptied during the intervals and that in order for this to be done even in wet weather sufficient covered playground should be provided. It will, too, be noted how much the carbonic acid was in excess of the standard usually accepted.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6537 births and 3672 deaths were registered during the week ending Nov. 19th. The annual rate of mortality in these towns, which had been 17·0 and 17·2 per 1000 in the two preceding weeks, declined again last week to 17·1. In London the rate was 16·6 per 1000, while it averaged 17·4 in the thirty-two provincial towns. The lowest rates in these towns were 8·8 in Croydon, 10·9 in Derby, 11·6 in Oldham, and 12·0 in Hull; the highest rates were 22·4 in Newcastle-upon-Tyne, 22·6 in Liverpool, 23·1 in Wolverhampton, and 24·2 in Preston. The 3672 deaths included 371 which were referred to the principal zymotic diseases, against 420 and 412 in the two preceding weeks; of these, 90 resulted from diphtheria, 84 from "fever" (principally enteric), 61 from measles, 61 from diarrhœa, 45 from whooping-cough, and 30 from scarlet fever. No death from any of these diseases was recorded last week in Plymouth; in the other towns they caused the lowest death-rates in Croydon, Oldham, Wolverhampton, and Birmingham, and the highest rates in Nottingham, Burnley, Swansea, and Norwich. The greatest mortality from measles occurred in Norwich and Nottingham; from scarlet fever in Burnley; from whooping-cough in Halifax; and from "fever" in Derby, Sheffield, Norwich, Preston, and Birkenhead. The 90 deaths from diphtheria included 44 in London, 8 in Sheffield, 7 in Liverpool, 6 in Swansea, 5 in Blackburn, 4 in Leeds, and 3 each in West Ham, Cardiff, and Leicester. No fatal case of small-pox was registered during the week under notice, either in London or in any other of the thirty-three large towns, and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Nov. 19th, was 3259, against numbers increasing from 2178 to 3138 at the end of the twelve preceding weeks; 319 new cases were admitted during the week, against 336, 318, and 340 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 237 and 248 in the two preceding weeks, further rose last week to 285, but were 136 below the corrected average. The causes of 41, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Bradford, Hull, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Swansea, Liverpool, Burnley, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·9 and 19·4 per 1000 in the two preceding weeks, further rose to 19·5 during the week ending Nov. 19th,

Digitized by Google

and exceeded by 2·4 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·8 in Paisley and 15·0 in Leith to 21·6 in Edinburgh and 23·0 in Aberdeen. The 588 deaths in these towns included 22 which were referred to diarrhœa, 14 to "fever" (principally enteric), 11 to diphtheria, 9 to whooping-cough, 8 to scarlet fever, and 6 to measles. In all, 70 deaths resulted from these principal zymotic diseases, against 80 and 86 in the two preceding weeks. These 70 deaths were equal to an annual rate of 2·3 per 1000, which was 0·6 above the mean rate last week from the same diseases in the thirty-three large English towns. The deaths referred to different forms of "fever," which had been 18 and 16 in the two preceding weeks, further declined to 14 last week, of which 8 occurred in Glasgow, 3 in Edinburgh, and 2 in Paisley. The 11 fatal cases of diphtheria corresponded with the number in the preceding week, and included 5 in Dundee and 3 in Glasgow. The 9 deaths from whooping-cough showed a decline of 2 from the number recorded in the preceding week, and included 5 in Glasgow. The fatal cases of scarlet fever, which had been 6 and 9 in the two preceding weeks, were 8 last week, of which 6 occurred in Glasgow and 2 in Edinburgh. Of the 6 deaths from measles 5 occurred in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 126 and 129 in the two preceding weeks, were 130 last week, and were 15 below the number in the corresponding period of last year. The causes of 36, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·8 and 30·0 per 1000 in the two preceding weeks, declined again to 27·7 during the week ending Nov. 19th. During the past four weeks the death-rate in the city has averaged 27·2 per 1000, the rate during the same period being 16·3 in London and 19·3 in Edinburgh. The 186 deaths registered in Dublin during the week under notice showed a decline of 15 from the number in the preceding week, and included 9 which were referred to the principal zymotic diseases, against 18 and 22 in the two preceding weeks; of these, 4 resulted from "fever," 2 from whooping-cough, 2 from diarrhœa, 1 from diphtheria, and not one either from small-pox, measles, or scarlet fever. These 9 deaths were equal to an annual rate of 1·3 per 1000, the zymotic death-rate during the same period being 1·5 in London and 3.3 in Edinburgh. The deaths referred to different forms of "fever," which had been 3 and 5 in each of the two preceding weeks, declined to 4 last week. The fatal cases of whooping-cough, which had increased from 1 to 4 in the three preceding weeks, declined to 2 last week. The mortality from scarlet fever showed a further decline from that recorded in recent weeks. The 186 deaths in Dublin last week included 45 of children under one year of age, and 39 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from those recorded in the preceding week. Nine inquest cases and 5 deaths from violence were registered; and 60, or nearly one-third, of the deaths occurred in public institutions. The causes of 11, or nearly 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are announced:—Staff-Surgeons: Horace Elliott to the *Philomel*, and Percy W. Bassett-Smith to the *Ganges*. Surgeons: Herbert L. Penny to Cape of Good Hope Hospital, George G. Borrett to the *Pembroke*, and Robert H. Mornement to the *Niobe*.

ROYAL ARMY MEDICAL CORPS.

The under-mentioned officers retire on retired pay: Lieutenant-Colonel Nicholas Leader and Lieutenant-Colonel Kenneth S. Wallis. Major Russell has embarked for Bombay and Major Freyer has arrived at Shorncliffe for duty. Major W. Dugdale is transferred from Bombay to the Nagpore District. Major Morse has embarked for India. Captain Tate and Lieutenant Penny embark for Sierra Leone. Lieutenants Nickerson and Hall join the Eastern District for duty, and Lieutenants Archer and Heffernan join the Dublin District for duty. Captain Blenkinsop embarks for service in West Africa.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the following promotions among the officers of the Indian Medical Service:—Majors to be Lieutenant-Colonels (dated Sept. 30th, 1898): *Bengal Establishment:* Terence Humphreys Sweeny, Daniel Francis Barry, George Francis Angelo Harris, John Anderson, Charles James Bamber, and Malachi O'Dwyer. *Madras Establishment:* Clement Mallins, Edulji Manekji Damla, and Herbert St. Clare Carruthers. *Bombay Establishment:* Charles George Walton Lowdell, Harry Beecham Briggs, and Walter Peter Carson. Captains to be Majors (dated Sept. 30th, 1898): *Bengal Establishment:* Robert Joseph Macnamara, Herbert Wilson Pilgrim, George Brooke French, Francis Wyville Thomson, Edwin Harold Brown, Charles Norman Bensley, Selby Herriot Henderson, David Wilson Scotland, Charles Robert Mortimer Green, James Henderson Sellick, Edward Christian Hare, Frank Cecil Clarkson, John Gregory Jordan, Herbert Mackinlay Morris, Allan Rupert Postance Russell, James Morwood, and Edmund Alexander William Hall. *Madras Establishment:* Richard Henderson Carter, Frederick George Maidment, and Ignatius Purcell Doyle, D.S.O. *Bombay Establishment:* Blenman Buhot Grayfoot and Thomas Edward Dyson. The Queen has also approved of the transfer of the under-mentioned officer to the Half-pay List: Lieutenant Ernest Le Fevre Payne (dated Nov. 3rd, 1898). The Queen has also approved of the retirement from the Service of the under-mentioned officers: Colonel Daniel Frederick Bateman, Madras Establishment (dated Oct. 31st, 1898), and Major Moscardi Bellarmin Braganza, Bombay Establishment (dated Sept. 15th, 1898).—*The London Gazette.*

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Clement Godson, 18th Middlesex Volunteer Rifle Corps, to be Surgeon-Major, and Surgeon-Lieutenant Albert Henderson, 1st Aberdeenshire Royal Engineers (Volunteers), to be Surgeon-Lieutenant.

MILITIA MEDICAL STAFF CORPS.

John Davies to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 2nd Hampshire (Southern Division, Royal Artillery): Paul McKenna Terry to be Surgeon-Lieutenant. 1st Lancashire: Frederick Francis German to be Surgeon-Lieutenant. *Rifle:* 3rd Volunteer Battalion the Welsh Regiment: Surgeon-Major E. Jones to be Surgeon-Lieutenant-Colonel. 1st Volunteer Battalion the Duke of Cambridge's Own (Middlesex Regiment): Surgeon-Lieutenant-Colonel F. Orton resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the battalion on his retirement. 2nd Volunteer Battalion the Highland Light Infantry: The under-mentioned officer resigns his commission: Surgeon-Captain W. B. Moir.

HOSPITAL TRAIN.

A correspondent writes:—"In the late war with Spain the United States not only made use of hospital ships but also of hospital trains. The hospital ships, although not altogether novel, were brought to such a degree of efficiency during the Hispano-American war that to all intents and purposes they initiated a new departure in warfare. The hospital train, however, is seemingly an absolutely new experiment. Mr. Sanbom, the gentleman who was in charge of it, thus describes it: 'The establishment of a regularly equipped hospital train is an entirely new departure in the time of war and to the United States Government the entire credit is due. Heretofore many inconveniences and dangers were met in transferring the wounded from the scenes of conflict, but it can now be done expeditiously and without the risk of aggravating wounds or subjecting the sick to undue excitement or the jolting incident to other forms of conveyance. This train is composed of 15 easy riding cars of Pullman build, very similar to the colonist sleepers. Twelve of these cars are fitted each with 30 berths, wash-rooms, lavatories, compartments for drugs, nurses' room, &c. Each car has its

Digitized by Google

own nurses, who are under the direct charge of an assistant to the head surgeon of the outfit. There is also a dining car with its chef and a corps of assistants which serves alike to patients, officers, and help. In addition to the Government rations there are provided many delicacies by the Ladies' Aid Society of the United States. This association also supplies quantities of night-shirts and underwear for the soldiers received into the hospital on wheels. Another car is fitted up as a complete operating theatre, with its varied assortment of instruments and furniture and a separate room for the disinfection of the soldiers' clothes. In this car is every appurtenance for an emergency surgical operation *en route*. Then there is a car devoted entirely to supplies, etc., and last, but not least, the rear car is fitted up as headquarters for the officers and surgeons. The train has its own locomotive, runs on a specially fast schedule, and is manned by the crews of the various systems over which it runs.'"

SIR FRANCIS GRENFELL AND THE ROYAL ARMY MEDICAL CORPS.

The *Army and Navy Gazette* says: Upon the return to Cairo of the Nile Expeditionary Force an address was delivered by Sir Francis Grenfell, the General Officer Commanding Her Majesty's Forces in Egypt, at a general parade on Oct. 8th:—

"Colonel Barrow, Officers, Non-commissioned Officers, and Men of the Royal Army Medical Corps,—I am glad of this opportunity of telling you of my high appreciation of the valuable services rendered by your corps during the late operations on the Nile. I regret that Surgeon-General Taylor and Colonel Macnamara are not present that I could personally thank them for their valuable coöperation. I have lately visited the hospitals at Atbara and Abadia, and was much pleased and greatly struck with their efficiency, by the care and attention shown to the sick and wounded, and by their general appearance of comfort. I can assure you that all branches of the service have been loud in their praise of the way that the sick and wounded were looked after both in the hospitals and on the field, and I may tell you that I have not heard a single adverse criticism with regard to the working of the medical arrangements."

The Director-General in a special order has recorded his extreme appreciation of the services rendered by the corps which have earned this commendation. The high character earned by all ranks of the corps certainly reflects great credit not only upon its members but also upon Surgeon-General Taylor, P.M.O., who has thus added to his reputation as an administrator.

THE ROYAL NAVY LIST DIARY FOR 1899.

All who are interested in the Royal Navy—and who is not?—will welcome the second annual issue of this useful naval handbook and diary. To mention some only of the contents, there is a Summary of the Year's Naval Progress, by Mr. L. Carr Laughton; complete schedules—monthly, quarterly, half-yearly, and yearly—for the recording of all drills and duties, and the making up of returns; obituary for the year, with the war and meritorious services of deceased officers; a calendar of notable naval events; and a detailed list of the benevolent funds and institutions in connexion with the navy, together with a brief statement of the objects for which they were founded. The diary gives a page to a day, and the whole book is complete in every respect. The frontispiece, "The First Line of Defence," which shows H.M.S. *Victory* off Cadiz in 1805, and H.M.S. *Illustrious* in 1898, is intended to illustrate the evolution of a first-class line of battleship in the nineteenth century. Messrs. Witherby and Co., 326, High Holborn, are the publishers, and the price of the diary is 3*s*.

THE STAFF OF THE NEW VICEROY OF INDIA.

Lieutenant-Colonel E. H. Fenn, R.A.M.C., who is at present, we believe, serving at Peshawar, has been selected for the appointment of surgeon on the Viceroy's staff. He held that post during Lord Lansdowne's Viceroyalty.

THE DIRECTOR-GENERAL OF THE INDIAN MEDICAL SERVICE.

Surgeon-General R. Harvey has proceeded on a tour of inspection in connexion with the duties of his new appointment as head of the Indian Medical Service.

LIEUTENANT-COLONEL FRANKLIN, I.M.S.

This officer returns with Lord Elgin, the late Viceroy. On his going back to India Lieutenant-Colonel Franklin will be appointed Inspector-General of Civil Hospitals, Punjab.

Correspondence.

"Audi alteram partem."

"THE QUESTION OF INDECENT LITERATURE."

To the Editors of THE LANCET.

SIRS,—With reference to your very fair and reasonable article on the questions that are raised rather than settled by a recent trial, will you allow me to state that the defendant was not the publisher of my "Studies in the Psychology of Sex"? He was not in any way connected with its publication, though he occupied premises formerly occupied by the publisher, and until these proceedings were initiated I was not even aware that he acted as an agent for its sale. It was stated in court that he sold in all three copies only.

You ask the very pertinent question: Why was not the book issued by a medical publisher? The answer is simple. None of the medical publishers whom I approached cared to take up a book on the subject of sexual inversion, one or two adding that they would have done so with pleasure had it not been their privilege to live in England. After a delay of two years due to this cause, I heard through a scientific friend that a gentleman interested in various philosophic and scientific subjects was preparing to go into business under a trading name for the publication of a few philosophic and scientific works and that he would be willing to issue my book. Ultimately I agreed to place the work in his hands on the definite condition that it should not be advertised or sent for review in any but medical and scientific quarters. In justice to the publisher I must point out that my book is the only one of his publications, mostly very serious in character, which has been incriminated.

With reference to your remarks concerning Ulrichs I should like to say that while I have inserted an appendix to my book (by another hand) expounding the views of that copious writer I do not consider that these views are of any scientific value and have explicitly rejected them. Ulrichs' writings are mainly of historical interest. He was himself an invert and he succeeded in directing scientific attention to the abnormality of which he was a victim. So far as standpoint is concerned, my own position is not materially different from that of Krafft-Ebing, though I am by no means in sympathy with the Viennese professor's treatment of these subjects. Certainly inversion when it arises on a congenital basis is "natural," but only in the same sense that all pathological anomalies are natural—colour-blindness, for instance, or hypospadias. I am not prepared to admit that congenital inversion is natural in any other sense.

I am, Sirs, yours faithfully,

H. HAVELOCK ELLIS.

THE EXAMINATION OF THE BRITISH OPTICAL ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—You make a comment in THE LANCET of Nov. 19th on the above in a tone of modified approval. If one may judge from the advertisements in the newspapers this association exists chiefly to furnish material for advertisements by its members. The prescribing chemist may be objectionable, but he does not generally do actual harm, whereas the consulting optician (or eyesight specialist) often causes harm and pain to young people who may consult him. My experience is that an emmetropic or slightly hypermetropic young person in his teens, doing some extra work and having a certain amount of spasm induced, is frequently by these advertisements lured to the "eyesight testing-rooms," where probably a couple of pairs of slightly differing low concave spherocylindrical spectacles are supplied, and then for a time the patient sees well, but ultimately in a few weeks worse spasm is induced and more pain.

The proportion of girls with defective visual acuity is greater than it is in boys at every age of school life; in them this spasm is exceedingly common, and it is girls who most frequently suffer from the wrong glasses of the

Digitized by Google

optician. The method, so far as I have been able to make it out as advertised, "Sight testing for the general practitioner," is on a level with that of the "honourable company" of spectacle sellers, being one which neglects spasm of the eye, and is on that ground to be condemned as likely to be unreliable if used to prescribe spectacles for young people. We now have our Board School children tested as to visual acuity, and errors of refraction become obvious as soon as young people go to work, so that glasses are becoming more necessary every day at earlier ages. The correction of the causes of the pain and inconveniences from refractive errors is part of a medical man's work and should not be allowed to pass into the hands of those who seem to be organising themselves into a vested interest; whilst at the same time their methods for the reasons given above are daily becoming unsuitable and actually harmful to increasing numbers of their patients.

I am, Sirs, yours faithfully,

JAMES KERR,

Honorary Surgeon to the Bradford Eye and Ear Hospital.

Bradford, Nov. 22nd, 1898.

*** We think the association will find our approval very modified.—ED. L.

THE TREATMENT OF TETANUS BY ANTITOXIN.

To the Editors of THE LANCET.

SIRS,—Mr. Stonham's case of tetanus recorded in THE LANCET of Nov. 19th is of much interest as a case of tetanus, but it could hardly be a matter of surprise that in so acute a condition the treatment with antitoxin should have failed. Every surgeon will, I think, agree that as a general rule the shorter the period of incubation in tetanus the more acute in all probability will be the course of the disease, and the greater the likelihood that whatever the treatment adopted the remedy will fail. It is in the chronic cases where the symptoms are delayed and are in themselves less severe that internal remedies, and antitoxin amongst them, have seemed to be of most use, but in all cases the suspicion may fairly be entertained that the disease might have passed away without them. But if antitoxin may seem to fail or to be of comparatively small value as a mode of treatment in the course of the disease it is possibly far otherwise when it is used as an immunising agent. Happily, I have not myself had a case of tetanus in my wards for many years, and the experience of other surgeons is doubtless the same, because of the care now taken in the cleansing of all wounds. I am unable, therefore, to speak from personal observation, but a great impression was made on my mind by a paper in the *Annals of Surgery* of December, 1897, by Professor Dennis of New York on the Treatment of Tetanus. In speaking of antitoxin as an immunising agent he says: "All surgeons agree that it would not be justifiable to immunise a patient on the vague supposition that tetanus might develop. The use of the antitoxin as a prophylactic measure is consequently limited to those cases where the wound has been inflicted in such a manner as to allow garden-earth, plaster from walls, or manured soil to come in contact with it, or where the traumatism has been caused by a rusty nail upon which the bacilli are discovered, or in a given locality where tetanus is prevalent, or where the wound is a lacerated one with entrance of foreign bodies into it." And then, having referred to the marvellous prophylactic influence of the diphtheria antitoxin, he goes on: "If such results follow from the use of antitoxin as an immunising agent in diphtheria it is logical to expect that even more brilliant results will ensue in the adoption of this treatment in tetanus, since the antitoxin of tetanus shows even better results in lower animals. Under such conditions immunisation is a proper line of treatment and one from which success is sure to follow. Bazy, a French surgeon, had 4 fatal cases of tetanus in his practice in one year and subsequently began injecting 20 c.c. of serum into all patients who suffered from lacerated wounds into which extraneous matter had of necessity entered. Since he adopted this practice tetanus has not followed in those cases in which a strong probability existed that this dreaded disease might develop. Lambert mentioned that Nocard in veterinary surgery immunised 375 animals and in no single case did tetanus develop, while he had 55 cases of the disease in animals in the same environment."

It is open, of course, to everyone to question the value of evidence like this, where the prediction of tetanus might never have been verified, but the evidence, to say the least, is very striking. It is, moreover, in accordance with all that is known of the disease itself and of the behaviour of antitoxins in general to draw the conclusion that the antitoxin of tetanus is more likely to succeed in warding off the disease altogether than in arresting or putting an end to it when the symptoms have developed—that really is to say when the mischief has been done. In recording a case of hydrophobia in THE LANCET of Feb. 8th, 1890, where opium and eserine had been pushed to their physiological effects without result, I wrote: "The fact of the matter, however, is this: that at that period of the disease no drug treatment can be of the least avail to stay the progress of the effects which the specific poison of rabies has wrought in the most vital parts of the nervous system. The antidote must begin its work at an early period and no unprejudiced mind can doubt that that is to be found in the inoculations of M. Pasteur." Immunisation against hydrophobia, a very similar malady, has long been above question. I would urge the like treatment in the case of tetanus whenever there is reasonable ground for fearing that it may arise. I cannot help thinking that the antitoxin will then be proved of greater value than the record of cases treated by it up to this time seems to warrant.

I am, Sirs, yours faithfully,

Nov. 22nd, 1898. HERBERT W. PAGE.

"PHARYNGO-MYCOSIS."

To the Editors of THE LANCET.

SIRS,—The attention which has been drawn to the subject of this disease, as treated of in Dr. Lubet-Barbon's work on the subject and reported in your columns,[1] is extremely well deserved, if we may judge by the alarm which is experienced when its presence is accidentally discovered—an alarm which is absolutely uncalled for. From a consideration of the histology of the condition I have been led to adopt a plan of treatment to which no reference is made in your report—namely, the application of salicylic acid which is known to have so marked an effect in breaking up and destroying masses of cornified epithelium. The opportunities for treating such cases are not common, but I have found this remedy more effective than any other. The mode of use is to twist a very thin layer of cotton-wool on the tip of a fine bent probe. This is dipped in a 25 per cent. solution of salicylic acid in alcohol and is then applied to each spot of pharyngo-mycosis. In the intervals the patient may apply a 5 per cent. solution in rectified spirits to which a small proportion of glycerine is added. Although I hit upon this method of treatment without suggestion from elsewhere I understand that it has already been employed by Spengler. I recommended the remedy to my friend Dr. Herbert Tilley, and was gratified to find that his experience of its use was as favourable as my own.[2] I may add that I have employed the remedy in cases of recurring papilloma of the larynx with most satisfactory results, and I believe that even in pachydermia of that organ I have obtained by its use beneficial results such as no other treatment at my hands has brought about. I have great expectations as to the value of salicylic acid in various diseases of the throat.

I am, Sirs, yours faithfully,

Upper Wimpole-street, W., Nov. 21st, 1898. DUNDAS GRANT.

"AGORAPHOBIA."

To the Editors of THE LANCET.

SIRS,—After reading the very interesting article on agoraphobia written by Dr. Headley Neale in THE LANCET of Nov. 19th I would like to draw attention to symptoms which he would doubtless attribute to agoraphobia that are referred to in a recent publication, "The Secret of Good Health and Long Life" (Bowden), but which I consider belong to acute "tea-poisoning." I am not one who would consider that agoraphobia is "all bosh" exactly, but I have found some of the very characteristic symptoms

[1] THE LANCET, Nov. 12th, 1898.

[2] Proceedings of the London Laryngological Society, May 11th, 1898.

Digitized by Google

Dr. Neale refers to in those who have been in the habit of drinking a lot of tea and who now and then take it very strong, particularly the fear of death or that something dreadful is going to happen, which symptoms have disappeared when tea-drinking has been stopped.

As regards giddiness or faintness and nervous seizures on hearing a great noise or on going up a high ladder, I would attribute these to ordinary liver, heart, or nervous conditions rather than count them pathognomonic of agoraphobia, knowing as I do that the best observers may be worked up to such enthusiasm over some pet, or perhaps personal, ailment that they may sometimes be inclined to put down almost every disease under the sun to—eating butcher's meat, say, for instance. Dr. Prosser White found that "moral determination" and "lively conversation" were good in the way of treatment. I have advised these methods also in cases of acute "tea-poisoning" with success. Moreover, Dr. Neale writes that "the avoidance of over-mental strain and of all excesses, a careful dietary, aids to digestion and tonics, will together contribute to a satisfactory issue and ensure the disappearance of this pathological 'spook.'" No doubt he also told most of his patients to drink weak tea or none. It would be interesting to know whether Dr. Neale was in the habit of drinking strong tea during his student days when agoraphobia used to seize him. Something kept him awake, what time lamps were outshone by the sun. I should think it very likely he did, under the "temperate and celibate" but withal "rushing" and hard circumstances under which he moved and had his being.

I am, Sirs, yours faithfully,

Buckhurst Hill, Nov. 21st, 1898. HAYDN BROWN.

THE "OPEN-AIR" TREATMENT OF TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—At the present moment probably nothing is attracting more attention both amongst the profession and the public at large than the possibility of grappling with that terrible scourge, tuberculous lung disease. The most rational and the recognised only satisfactory method of dealing with this disease is what is called the "open-air" method, and to carry out this treatment it is proposed to establish in England sanatoria with the object of so dealing with tuberculous lung disease. Now there is no question that the erection and maintenance of these buildings, wherever they are, will absorb a large amount of capital and a considerable expenditure annually. If all that is talked about and expected of these places were one-tenth realised, looked at from a charitable view only, anything would seem justifiable, but it is because I have very grave doubts of their success in treating the disease in question that I would ask you to publish these facts as to what the "open-air" treatment really is, or should be, and whether it is possible even in a small degree to carry it out in England.

Its primary and essential point is—out of doors all day and till bedtime (i.e., from 8 A.M. till 10 P.M.) except for meals. The conditions under which this is carried out in the various continental health resorts are as follows. There is almost perpetual bright sunshine from 9 A.M. till 4 P.M. in mid-winter and longer as the season alters; the air is of an extreme dryness, and this is probably one of the two most important points, the other being height, from 5000 ft. to 6000 ft., with the barometer standing from 24 in. to 22·5 in., the constant automatic expansion of the lung going on under the greatly reduced pressure, causing around cavities and deposits an emphysematous zone which cuts them off from the healthy lung; the great purity of the air caused by the cold and the surrounding snow and brilliant sunshine—the finest germicide known; the almost total absence of wind which no affected lung will stand, and the actual great heat and brilliancy of the sunshine, shining through the rarefied air with great power, without the intervention of an obstructing dense atmosphere;—these, then, are the conditions which enable a tuberculous patient to be out in the balconies or walking out in the snow from daybreak till bedtime, and hence the favourable results; it is, in fact, the nearest approach to treating the lung aseptically that is possible. We cannot treat it as we do any other wounded portion of the body, we cannot dress the cavities in it, but we can apply very dry aseptic perfectly pure air day and night (for the windows are open at night, with the thermometer 10° or more below zero), and this aseptic treatment of the lung is very successful.

Now let us turn to the suggested treatment in England; and I may say at once that almost every necessary condition is wanting. The sun is often absent and without power, the air is certainly often far from pure—it is during a greater part of the winter saturated with moisture, and this is most important as it almost seems as if moist air is an exciting cause of tubercle, certainly almost an incubator for the bacillus. There is constant wind from all directions—S.W. laden with moisture, N.E. biting and often damp. There is no reliable dry cold of any duration and there is no possibility of producing expansion of the lung from rarefied atmosphere in England. It is evident from this that all the conditions recognised as necessary are absent from our climate, and there are but few days in the winter and early spring in England when a patient with tuberculous lung disease could lie out of doors all day or walk about. Face which way the balconies or promenades in England will, they would be liable to be invaded with drifting rain or sleet and blown out with gales of wind. The result would be that they would be closed in and then the "open-air" treatment ceases to exist. I am sure that upon consideration many will agree with me that it is impossible in England to satisfactorily, even in a small degree, carry out the treatment I have indicated and which is the method pursued on the continent. To my mind all the necessary conditions are absent, and as it used to be said that "bricks could not be made without straw," so it seems to me that it is well to pause and consider before embarking on a scheme which will probably end in great disappointment to both patient and medical man, and which seems to me to be trying to do the "impossible." No one can deny that as much "fresh air" as possible is a great improvement on the horrid old system of stuffy rooms and hot air for tuberculous lung diseases; but that the "open-air" treatment can be pursued in England during an English winter, where not one single necessary condition is present or can be obtained, seems to me to be perfectly impracticable. One day spent out of doors, followed by two or three in the house because of mist, fog, wind, or rain, or cold without sun, would more than undo any good which had been obtained, and that seems to be the best which can be hoped for. I have written at great length on a very important subject and I hope it may elicit the opinions of medical men more competent to judge than I am. But I do think the questionable benefit may follow the partial open-air treatment I do not deny, especially to patients removed from their insanitary surroundings. But under the climatic conditions, both present and absent, I do not think that we can look for, or hope to see, many, if any, actual cures—the conditions would conduce to the opposite direction.

I am, Sirs, your obedient servant,

Nov. 14th, 1898. A. G. P. GIPPS.

To the Editors of THE LANCET.

SIRS,—I pointed out some years ago[1] that the late Dr. George Bodington, of Sutton Coldfield, Warwickshire, was the first to devise and carry out the present system of generous diet and open-air exposure for the cure of consumption. In those days (1840) before the theory of "phlogiston" had collapsed under the influence of microscopic pathology, he had many difficulties to contend against, and his plan of treatment, although successful with a certain number of cases, met with such derision and contempt that he finally gave up the practice, taking lunatics into his house-sanatorium instead of consumptives—a laudable course to pursue in his case, as he was returning good for evil to the class who criticised and reviled his project. The effect of adopting a suitable diet and fresh country air for the treatment of phthisis is rather ancient history, but Dr. Bodington grasped the points of their efficacy and brought these remedial agents into systematic working order. Much that he has written in a faded little volume of some 60 pages might be reproduced as a fresh article on the dietetic and open-air treatment of consumption. Why so many writers on this

[1] Alpine Winter in its Medical Aspects, 1884.

Digitized by Google

subject represent the method as having been "made in Germany" I am unable to say. Certainly Dr. Brehmer carried it out with satisfactory results in 1860, but the plan had been clearly laid down and described by Dr. Bodington, who practised it twenty years previously to Dr. Brehmer and who published his success with the cases which submitted themselves to his scheme of treatment.

Our attention has been directed recently to the remarkable results reported as having occurred under the system of feeding and fresh air as conducted in the Black Forest, a climate which has been compared with that of the English lake district, in winter. There is no question as to the efficacy of over-feeding and fresh air in those cases which are fortunate enough to possess digestive organs fairly strong and unimpaired, but we must not lose sight of the important part which climate plays—especially mountain air—in the cure of pulmonary consumption. One good effect following the success of sanatoriums established in inferior climates will be to stimulate the scheme of providing similar institutions in England, where a great deal of what is lacking in "climate" can be made up in a nutritious and digestible dietary. There is no country in Europe where good food is so cheap and abundant, nor meat, fish, poultry, and game of a better quality. The advantage also of patients being treated by medical men of their own nationality, who have an intuitive knowledge of the national constitution, are familiar with the habits and customs of English people and their requirements, is not to be forgotten.

Personally, I am sorry to see our well-tried old remedy—alpine climate—temporarily slighted in favour of rival sanatoriums with quaint innovations, but in the main simply carrying out effectually the treatment originated by Dr. Bodington, from whose "Essay on the Cure of Pulmonary Consumption on Principles Natural, Rational, and Successful" I may be permitted to quote. He writes:—

"I should recommend to one thus consuming away under the influence of this *wasting disease* a nutritious diet of mild, fresh animal and farinaceous food aided by the stimulus of a proper quantity of wine, having regard to the general state and condition of the patient. ..... I have, as will be found by a perusal of the following pages, employed a nutritious and moderately stimulating diet with much success; and without that I do not think the other means could have been so effectual or the treatment complete. ..... I have taken for the purpose a house in every respect adapted, and near to my own residence, for the reception of patients of this class. ..... It is presumed that the advantages to be derived from systematic arrangements with regard to exercise, diet, and general treatment, with the watchfulness daily, nay, almost hourly, over the patient of a medical superintendent, great advantages may be obtained by the consumptive patient treated in this way."

Speaking of the therapeutic agents in use at that time (in 1839) he continues:—

"One mode of treatment consists in shutting the patients up in a close room, to exclude, as far as possible, the access of the atmospheric air, and thus forcing them to breathe over and over again the same foul air contaminated with the diseased effluvia of their own persons. ..... This is, indeed, a treatment founded on the most erroneous principles."

Referring to the inhalation of gases of various kinds Dr. Bodington says:—

"The only gas fit for the lungs is the pure atmosphere freely administered without fear; its privation is the most constant and frequent cause of the progress of the disease. To live in and breathe freely the open air, without being deterred by the wind or weather, is one important and essential remedy in arresting its progress, one about which there appears to have generally prevailed a groundless alarm lest the consumptive patient should take cold. ..... Farmers, shepherds, ploughmen, &c., are rarely liable to consumption, living constantly in the open air, whilst the inhabitants of towns and persons living much in close rooms, or whose occupations confine them many hours within doors, are its victims. The habits of these latter ought, in the treatment of the disease, to be made to resemble as much as possible those of the former class, as respects air and exercise, in order to effect a cure. ..... I come now to the most important remedial agent in the cure of consumption, that of the free use of a pure atmosphere. The abode of the patient should be in an airy house in the country. ..... The patient ought never to be deterred by the state of the weather from exercise in the open air; if wet and rainy a covered vehicle should be employed, with open windows. The cold is never too severe for the consumptive patient in this climate; the cooler the air which passes into the lungs the greater will be the benefit the patient will derive ..... and means applied to stimulate and invigorate the nutritive, sanguiniferous, and muscular powers; wine and such nourishing diet as the stomach could bear and by means applied to soothe and allay nervous excitement locally and generally. ..... Apartments should be kept cool and airy, corresponding to the external atmosphere, which should be courted and indulged in to the utmost."

After impressing on the reader the necessity of a generous diet, consisting of fresh meats, eggs, farinaceous food, beef-tea, milk, &c., as much as the digestion could bear, with wine or wine and water, according to circumstances, he concludes by the relation of some cases and a reiteration that the bedroom should be cool, airy, and properly ventilated and the sitting-room should have the windows wide open. I have quoted Dr. George Bodington at some length in the endeavour to point out by his own words and practice that we must regard him as the originator and introducer of the modern treatment of pulmonary tuberculosis. I am not aware of anyone having forestalled him in clearly laying down the principles which now guide us in all health resorts and sanatoriums devoted to the cure of consumption. Dr. Bodington must be accredited, too, with the courage of his opinions, for in those days of antiphlogistic remedies it was a bold, intelligent innovation deserving of all recognition and praise. Even that distinguished physician Sir James Clark sarcastically alluded to it at the time as the "beef steak and porter system," which he decidedly condemned.

I am, Sirs, yours faithfully,

A. TUCKER WISE, M.D. Brux., Diplôme Suisse Fédéral, M.R.C.S. Eng., L.R.C.P. Lond.

Montreux, Switzerland.

"THE WATER TEST AS APPLIED TO SEWER CONNEXIONS."

To the Editors of THE LANCET.

SIRS,—I, like your three previous correspondents (*vide* THE LANCET of Oct. 29th and Nov. 12th), have never been quite satisfied with the manner in which the portion of the drain between the intercepting trap and the sewer is put in by the authorities' workmen or contractors in London or elsewhere or of the connexion in the sewer. When, however, one is aware of the seriously unsound condition of main sewers, and thereby the greater contamination of soil and earth currents, and their ready conducts into the residences by means of water and gas pipes and the larger conduit outside the drain, also the contamination of water-supply *vid* unsound pipes or joints of the water-mains, the outcry against this small portion of probably unsound drain is very much like "jumping at gnats and swallowing camels."

Old practical sanitarians have by their experience always been convinced of the benefit inmates of houses with sound drains obtained in improved health and vitality, and I hope that serious attention will be drawn to the dangerous condition the sewers of London (and also our principal health towns) are in, more especially where towns are sewered upon the "combined" system, in consequence of the correspondence commenced in THE LANCET, and still greater benefits to health obtained to a larger number of people.

I am, Sirs, yours faithfully,

DANIEL THOMAS BOSTEL, R.P.C.

Ebury-street, S.W., Nov. 16th, 1898.

"A NEW SYMPTOM IN PARALYSIS AGITANS."

To the Editors of THE LANCET.

SIRS,—The new symptom to which Dr. Purves Stewart draws attention in his interesting paper in THE LANCET of Nov. 12th is present in a case now under my care. The patient, a woman, complained to me about a month ago of this "curling up" of the toes on the right foot. I have seen her this morning and the symptom was described to me again. It almost always occurs after walking about 200 yards, generally commencing in the third toe and rapidly spreading to the others, including the big toe. Walking is then very painful and soon impossible, although she has often persisted for a time by treading on the side of the foot or heel only. The "curling up" itself is not painful and passes off at once on her sitting down. Any little excitement when walking is apt to produce it immediately. In this case it was not an early symptom, the disease having declared itself some months previously. As this is the only case of paralysis agitans under my care at the present time it is, I think, an interesting corroboration of Dr. Stewart's observation.

I am, Sirs, yours faithfully,

W. J. ERNELY SUMPTER, L.R.C.P. Lond., &c.

Sheringham, Nov. 15th, 1898.

THE ANNUAL MEETING OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—A very important question underlies that raised at this meeting concerning the abuse of medical aid associations. It is whether our profession has a right to enforce its unwritten laws on its members. These laws consist in essence of the opinions of the great majority of the profession. There can be no doubt as to this opinion so far as advertising and canvassing in a direct form are concerned, and the Council of the College has often imposed an extreme penalty. Can there be any doubt whatever as to the views of the profession at large on this most flagrant form of the same offences carried on in the name of their medical officers by these trading associations? Why, then, should there be any difficulty in putting a stop to the scandal? Is it not high time that the corporations should more readily and promptly reflect professional opinion? Laymen, whether as individuals or as associations, must be shown that professional services can only be rendered under professional conditions. This doctrine will be called by some trades-unionism. It is, however, nothing of the kind, since it is entirely in the public interest that the profession should retain its independence. As Mr. Bryant says: "It is all-important for the interests of the public as well as for the due exercise and dignity of our profession that every practitioner of medicine should hold a perfectly independent but responsible position and that in his professional work he should be left entirely free from lay control, though amenable to lay censure. It is also necessary that he should be adequately paid by all classes according to their means."[1] The modern trading medical society is entirely subversive of these principles, and we call on Mr. Bryant to make good his words on the Council of the College.

I am, Sirs, yours faithfully,

Nov. 19th, 1898. W. G. DICKINSON.

RESECTION OF INTESTINE.

To the Editors of THE LANCET.

SIRS,—May I ask you to correct a slight error in the report in THE LANCET of Nov. 19th of the case I brought before the last meeting of the Clinical Society of London? The bowel removed measured 27½ in., not 24½ in. as stated.

I am, Sirs, yours faithfully,

R. CLEMENT LUCAS.

Wimpole-street, Cavendish-square, W., Nov. 19th, 1898.

"THE DIPLOMA IN SANITARY SCIENCE OF THE ROYAL UNIVERSITY OF IRELAND."

To the Editors of THE LANCET.

SIRS,—Dr. C. L. Birmingham has, in THE LANCET of Nov. 12th, directed attention to a defect in the title of the diploma in hygiene which the Royal University of Ireland offers to its own graduates and he cites, as a result of this defect, the interesting information that not one candidate has presented himself for that particular qualification during the past seven years. Certain it is that the title of "Diplomatist in Sanitary Science" savours very much of the qualification of a sanitary inspector and it is equally certain that it is not appreciated by Royal University medical graduates, who prefer to qualify elsewhere in public health. At the last examination for the D.P.H. of Cambridge at least 3 of the 14 successful candidates were Royal University men. Why should not the Royal University emulate Cambridge and hold D.P.H. examinations twice yearly, open to all qualified men who have completed the prescribed curriculum? As a young university it should be far more progressive and offer in addition degrees in hygiene to its graduates. Many who do not care about the "Diploma in Sanitary Science," so named, would be proud of a B.Hy. or a D.Hy. A gold medal offered annually would constitute an additional stimulus to the study of hygiene. There is an enormous amount of public health legislation demanded in Ireland and if its execution is to be efficient not only must great facilities be offered for the study of hygiene, but the universities must be alive to their duties and responsibilities in this matter. I hope that the Senate of the Royal University will earnestly consider Dr. Birmingham's suggestions. The Royal College of Surgeons is the only body in Ireland granting a D.P.H., but its examination should be raised to an average standard.

I am, Sirs, yours faithfully,

J. E. O'CONNOR, M.B. R.U.I., D.P.H. Cantab.

Lowestoft, Nov. 21st, 1898.

[1] THE LANCET, Feb. 10th, 1894.

INQUEST FEES FOR HOSPITAL MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—Will you kindly tell me in your columns whether I am entitled to a fee for attending an inquest under the following circumstances?

I am medical officer of a hospital and was ordered to appear at the coroner's court last Wednesday to give evidence as to the death of a child in the hospital, following an injury three weeks before. No fee was forthcoming, the coroner telling me that I was not entitled to one. I understand that the medical officers of infirmaries now get inquest fees in such cases, and I think my position is precisely the same as theirs, as I have to contribute to a superannuation fund under the Poor-Law Officers' Superannuation Act. I am, Sirs, yours faithfully,

Nov. 20th, 1898. A.M.O.

*** Medical officers of Poor-law infirmaries in the metropolis are entitled to fees for evidence, but medical officers of hospitals were left unaffected by the new arrangement of 1892 and are not entitled to fees for evidence. The Poor-law Officers' Superannuation Act does not affect our correspondent's position in this matter.—ED. L.

FEES TO PUBLIC VACCINATORS.

To the Editors of THE LANCET.

SIRS,—If any of your readers who are public vaccinators in the country have already come to an agreement with their board of guardians as to the scale of fees to be paid for work done under the new Act I should be greatly obliged if they would kindly furnish me through the columns of THE LANCET with the amount of such fees and as to whether postage is to be paid by the board of guardians or otherwise. I am, Sirs, yours faithfully,

Nov. 21st, 1898. PUBLIC VACCINATOR.

"THE ETHICS OF CLUB PRACTICE."

To the Editors of THE LANCET.

SIRS,—I agree with all "Constant Reader" says *re* clubs and club patients in THE LANCET of Nov. 19th. My way is to do exactly as I think best and show the club members that I care nothing at all for their opinions in any way whatever and if they do not like it they need not. I have little or no trouble; only once have I attended a meeting to reply to any complaint, and on that solitary occasion, after showing that the complaints were uncalled for and that I should always act in the same way, I tendered my resignation, but was at once met with a vote of confidence at the rate of 100 for to 4 against. It is the very worst thing to pander to any of the whims of club patients. I do my best, but I do it my own way, for all the clubs I have. I am, Sirs, yours faithfully,

Nov. 21st, 1898. ANOTHER READER.

VACCINATION AT CARDIFF.—At the meeting of the Cardiff Board of Guardians held on Nov. 12th it was decided, from January next, to act upon the advice of the Vaccination Committee and to appoint a medical man not engaged in private practice to act as public vaccinator for Cardiff under the new regulations provided by the Vaccination Act, 1898. At present there are three public vaccinators for the town districts of Cardiff. A letter was read at the meeting from the honorary secretaries of the Cardiff Medical Society, stating that in the opinion of the society it would be unwise to disturb the existing vaccination appointments.

THE EPIDEMIC OF TYPHOID FEVER AT BELFAST.

SECOND YEAR.

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 1360.)

THERE are some features about the prevalence of typhoid fever in Belfast which, at first sight, seem somewhat puzzling and not in keeping with what might be expected. On closer examination, however, explanations of at least a plausible character may be obtained. For instance, on the west bank of the Lagan the older and low-lying quarters are more exempt than the higher and newer districts. These latter which stretch out on either side of the Shankhill- and Crumlin-roads seem to be more favourably situated. Also many persons have gone to higher levels so as to live on sandy soil and have suffered in consequence. There is much to be said in favour of sandy soil; but in a town like Belfast where, as it will be shown, the most cruel callousness has prevailed in respect to sanitation, it is far from safe. The fact that the soil was sandy and readily absorbed liquids has led to the greatest carelessness in the construction of drains. Indeed, in some instances it was found that no attempt had been made to connect private drains with the public sewer. After wandering some distance the drain stopped. The liquid matter would filter through the sand and it was only after a considerable time that the solid deposits accumulated to such an extent as to entirely block up the sewer. The nuisance became so urgent that the drain had to be dug up, and then only was it discovered that no connexion had been made with the sewer. Of course this could be rectified, but in the meanwhile the subsoil had become thoroughly contaminated. Apart from such gross defects as this, many drains and branch sewers have been unsatisfactorily constructed and are constantly leaking. Sand is an excellent filtering medium, it therefore retains on the spot the foul matter contained in the water of the sewage. This matter ferments, decomposes, and gives off effluvia, which readily ascend through the sand and are breathed by the inhabitants who pass or live close by. Thus a house built on sandy soil may be extremely unhealthy though it may be topographically speaking well placed. The houses in the lower part of the town which are apparently not so well situated rest on a plastic, blue, soapy clay which has some sand in it. The district is damp and waterlogged because it is barely above the high-tide level. On the other hand, the soil is not porous. Soiled water with its contents flows away. In any case such effluvia as may be generated underground cannot rise up through the clay. This fact is demonstrated when any gas-pipe gets out of order. The odour of the gas does not rise into the street. Eighteen inches of this clay soil seem sufficient to keep out the smell of the gas which, however, is noticed when this amount of the boulder clay has been removed from the spot where there is a leak in the gas-pipe. Now, many of the houses in the older part of the town, where at first sight it would be natural to expect that numerous cases of typhoid fever would occur, are built on this clay soil, and this may in a measure explain why, instead of suffering more, they have suffered less than other districts. Yet there are low-lying districts on both sides of the river, but more especially on the County Down side, where many cases of fever have occurred. It will, however, be found that for the most part the houses are here built not on the clay but on what was formerly hollow ground which has been artificially filled up not only with road sweepings but also with the foul contents of privies and ashpits.

Hence we may, with some degree of certitude, conclude that the incidence of typhoid fever is in part due to the contaminated character of the subsoil. But there are many other causes. There is notably the question of sewer ventilation. The high level main sewer is some 30 ft. below the street. It had to be constructed by tunnelling. Perhaps it was laid at this great depth so as to drain more distant districts which are at a lower level, but whatever may be the explanation the fact remains that this main sewer has become a tank sewer. For about sixteen hours in the day, instead of carrying the sewage right away to the sea, it gradually fills up. As the sewage accumulates in this locked-up sewer it must of necessity displace the air which the sewer contains and force it up into the town. When the state of the tide permits the discharge of the sewage into the salt waters of the Belfast Lough air is drawn down into the sewer. As the sewage has been stagnant for several hours heavy deposits must have been formed and the question arises whether the final but long-delayed outrush of the sewage is strong enough to remove these deposits. Even such deposits as are moved forward are stirred up in the process and must give up effluvia. With the effluvia the air which comes in to replace the water is freely mixed. It also comes into contact with the filth still adhering to the side and bottom of this great sewer. The air has every opportunity of being corrupted. Then the mouth of the sewer is closed, and as the sewage accumulates the air thus rendered foul is forced back into the town. The main sewers are, in fact, like a big lung which breathes in the air of the town for some four hours, pollutes it in every way, and then breathes it back again into the town for eight hours; thus the process is repeated twice in every twenty-four hours. The breathing, if it may thus be described, is sometimes much heavier than the normal, and then a much greater quantity of sewer air is forced up into the streets and houses. This is due to the accumulation not merely of sewage but of rain-water. If the rains are heavy not only is the main sewer filled but so also are many of the branch sewers. At times the volume of rain-water exceeds the holding capacity of the sewers and very disastrous floods ensue. By connecting little streams which drain outlying districts with the main sewers the probability and frequency of floods have been increased. The backwash thus occasioned has been known to flood the High-street, which, in spite of its name, is on the low level, and the water in this street has accumulated to the depth of 18 in.

Nor are floods occasioned only by the fact that the main sewers are not large enough to act as reservoirs capable of storing the rainfall of several hours. Some of the branch sewers are not large enough to carry away with sufficient promptitude an extra heavy rush of water. They therefore overflow. Thus, there have been floods even at an altitude of 90 ft. above the sea-level. On the other hand, these sewers, which at one moment are not large enough, are in normal weather far too large to be self-cleansing. For this purpose a sewer should be half full of water at least once in the day, so that the whole of the lower half of the circle or oval may be thoroughly swept by the water and all adhering deposits carried away. It was because these sewers were not sufficiently flushed that some of the small streams were conducted to them, and this arrangement is very useful in dry weather, but with very heavy rainfalls it may occasion floods. It will thus be seen that the main drainage scheme is altogether defective. Tide-locked sewers are absolutely indefensible, nor can the outfall be considered safe. It consists of a wooden shoot or trough. Piles were driven in on each side, but the ground was so unstable that the driving in of one pile would sometimes force out a neighbouring pile. This wooden trough is, so to speak, floating on a moist soil and is therefore very likely to become defective. Under these circumstances the whole of the sewage may not be carried out as far as is intended and thought desirable. In any case it is said that some cockle-beds on the coast near Belfast have been contaminated. Some of the cockles from these beds are very large but have a suspiciously black appearance. One curious fact may be noticed in this respect. There are not many Jews in Belfast, but the colony is compact. It consists for the most part of immigrants and refugees from Poland and Russia who are particularly strict in their religious observances. Consequently they never eat any shellfish and eschew with pious horror the allurements of the cockle stall. Now it is a remarkable fact that not one of these Jews has suffered from typhoid fever. Nevertheless it would not be safe to conclude that abstention from eating cockles is the only reason which can explain this favourable circumstance. The fact that in Russia they were bred and born amid the most insanitary conditions is more likely to have rendered them immune. This latter theory meets with some confirmation from the experience of the Christian population. It has been observed that the number of policemen who have suffered from typhoid fever is altogether out of proportion to the rest of the population. But, on the other hand, the policemen for the most part are not natives of Belfast. They generally come from country districts where more healthy

Digitized by Google

conditions prevail. Consequently they are not immune and readily fall victims to the poisonous atmosphere of the town. The same observation is made with regard to the civil population of Belfast. There are many more cases of typhoid fever among the new-comers than among the old inhabitants. This is a condition which will be found to prevail in several other towns where typhoid fever is endemic. The natives are comparatively free from the disease; while in the barracks the recruits from other districts and the strangers who come to the town readily contract the disease. At Belfast not only have the comparative strangers supplied a larger contingent of cases, but the proportionate rate of mortality, especially among the police, has been higher. The Constabulary force in Belfast numbers about from 700 to 800 men. One of the barracks stands on bad soil; still in many respects the men lead healthier lives than a large part of the population and physically they are an exceptionally fine set of men. It does seem, therefore, that they have suffered because they are not accustomed to the unwholesome surroundings of town life. They have not been in the habit of breathing the air which the rising waters in the sewers force up into the streets. They have not lived on soil partially formed of the contents of privies or contaminated with organic matter which has escaped from leaking drains. These are conditions which even a stalwart Irish constable cannot always resist.

Nov. 21st.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Native Practitioners and Inoculation for Plague.—The Progress of the Epidemic.—The Native Chiefs' Institute of Public Health.—The Plague Commission.

THE present position of prophylactic inoculation for plague has been recently discussed at a meeting of the Bombay Medical Union. This is a large society composed entirely of native medical practitioners, and the subject was brought forward on purpose to discuss the strictly scientific aspect of the question. M. Haffkine attended and answered numerous inquiries concerning the results as well as the technique of the process. Although the statistics are very satisfactory they were not accepted by many members without cavil, and several evils were attributed to the operation, although not on very good grounds. The chief figures have been already published. The chairman, however, gave some statistics which went to show that those who were inoculated more than once enjoyed greater immunity from attacks of plague than those who were only once inoculated. The importance of the assistance of the native qualified medical practitioner in furthering the process of inoculation is very great, especially as the process can hardly be said to have "caught on" in Bombay. It is therefore satisfactory to know that the following resolutions were passed at the meeting :—

1. This meeting is of opinion that considering the data now available and the satisfactory result of the observations collected regarding the protective effect of Professor Haffkine's plague prophylactic the time has now arrived for the profession to make a definite pronouncement on the subject and invite the public to resort freely to the protective treatment as the only safeguard against plague. 2. The immunity derived from inoculation when done with a full dose appears to last for at least six months, but there is the possibility of its lasting much longer. 3. From the observations collected lately it appears that a second inoculation done ten days or so after the first further reduces the incidence of plague in those who resort to inoculation, and it is likely that a third inoculation, if such be practicable, would increase the immunity still further. The public are therefore invited to resort to at least two inoculations and even to a third if practicable. The duration of protection is also likely to be enhanced by such a repetition. 4. This meeting of medical men who have had a wide experience of inoculation in persons of all positions, ages, and constitutions, declares emphatically that rumours of inoculation originating different diseases, such as leprosy, syphilis, &c., are devoid of any foundation; that, considering the nature of the prophylactic which does not contain any living germ, such an eventuality is absolutely impossible; and that there are no facts to show that inoculation aggravates any existing ailments despite the rare and isolated instances which may at first suggest such an idea.

I hear that inoculation has been so popular in the Dharwar District that it has been found possible to make a small charge towards covering the cost of the operation

The following figures are very suggestive. Up to Oct. 21st there were in Dharwar town :—

	Persons.	Attacks.	Deaths.
Once inoculated	5712	 69	 31
Twice inoculated	3349	 9	 5
Uninoculated	5614	 957	 756

The flight of large numbers of the people, and these almost entirely of the uninoculated, gives the impression of greater virulence than the figures actually warrant, but even if the percentage were reduced to half it would still indicate the enormous value of these inoculations.

The decline in the plague mortality in Bombay city continues and expectation that the third outbreak was an abortive one and practically over finds confirmation. The weekly mortality has now almost descended to its normal number. There is also a decline in the virulence of the epidemic in other parts of the Presidency. During the previous week there were over 5000 deaths from plague but this has been reduced by nearly 500. The week's totals of 5927 cases and 4651 deaths, however, hardly attract the attention such a mortality demands. The continuance of occasional cases in Karachi is very suggestive, and amongst other things points to the probability of a recrudesence in the near future. Immense improvements have, however, been made in the sanitary condition of the city, so that the chances of a return of the epidemic in its former virulence are much diminished. The occurrence of 2 cases in the Punjab after a long interval of apparent cessation is very disquieting. The immense processes of scavenging, disinfection, and general cleaning up which have been accomplished in consequence of the plague have been in numerous places blessings helping to compensate for the disasters of the disease.

The proposed Indian Pasteur Institute languishes partly from want of funds and for this reason it has been decided by the central committee that any attempt to start an institution for the sole purpose of antirabic treatment was out of the question. Fortunately, the Native Chiefs' Institute of Public Health is likely to take practical shape. It is reported that over twenty lakhs of rupees have been collected for the health scheme, which will include the Pasteur treatment. We seem, therefore, to be within measurable distance of the establishment of the long-looked for institution—the absence of which is a discredit to Indian medical administration

I have referred to the mild but equally effective measures now adopted in Bombay as compared with the policy of the late Plague Committee. The Commissioner has lately submitted an outline of the measures which are now in progress for dealing with the plague. In the detailed instructions issued to the district officers considerable latitude is allowed in the direction of relaxation. In addition to the general measures—viz., removal of the sick to hospitals, observation of "contacts," and evacuation and disinfection of affected houses—particular attention is paid to the following points. Inoculation is being encouraged (this, however, has barely affected one-thirtieth of the population); rats are being destroyed; arrangements have been made for the local preparation of Lustig's serum (not yet shown to be of much value, however); the different communities are being assisted to form health camps and hospitals of their own; arrangements have been made for tile-turning; and a systematic survey of houses is being made with a view to their sanitary improvement. In addition passes and detention camps for travellers by railway have been abolished. It must be noted that all the measures now in force depend upon the assistance of the native volunteer committees—the object being to discover plague cases. There is no hesitation in saying that the object is only very partially achieved, but some of the measures are doubtless effective and the general plague administration works much more smoothly than before.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Proposed Hospital in Liverpool for Chronic Diseases of Children.

A NUMBER of ladies and gentlemen interested in the promotion of a hospital for the treatment of the chronic diseases of children on open-air lines in the vicinity of

Digitized by Google

Liverpool held a meeting at the Deaf and Dumb Institute on Nov. 17th. The chair was taken by Dr. William Carter. Dr. C. J. Macalister, in strongly advocating such an institution, wished it to be understood that it must not be confused with a convalescent institution but must be conducted on the lines of a hospital, suitably placed and providing for a long period of residence on the part of the patient. It should not be affiliated with any special hospital, as that would practically limit the recipients of its benefits to the patients of that particular charity. Mr. Robert Jones also strongly urged the claims of such a hospital and said that in this matter we were far behind our continental neighbours. The argument that our climate was unfitted for open-air treatment no longer carried weight. It was necessary that children should be treated under the best hygienic conditions, and these were only to be found in the country. Having occasion to visit a small French village near Boulogne he had been much interested in visiting three hospitals there which were built for children, one containing 1000 beds, another 300 beds, and another 30 beds. The convalescent home was of incalculable benefit as an annexe of city hospitals, but it did not fulfil the *rôle* of a hospital in the country where cases could be taken in to be cured and where no time limit would be prescribed, and where the prevention of deformity would be the aim. A resolution was unanimously carried "that a committee be formed for giving definite details of the scheme and for furthering the object of the meeting."

The Royal Southern Hospital: Annual Dinner; Proposed School for the Study of Malaria.

The ninth annual dinner in connexion with this hospital was held on Nov. 12th at the Exchange Station Hotel. Dr. William Carter, in his reply to the toast of "The Royal Southern Hospital," claimed for the hospital priority in Liverpool in accepting the antiseptic principles enunciated by Lister. He also alluded to the special opportunities enjoyed by the hospital for the treatment of malarial diseases, a fact recognised by the Government in subsidising six beds for such cases after the late Ashanti war. Principal Glazebrook of University College, in responding to the toast of "The Visitors," advocated the establishment by the Government of a school in Liverpool for the study of malaria. From its connexion with the West Coast of Africa Liverpool was more likely to have such cases than even London, near which, at the Albert Docks, the establishment by Government of such a school was contemplated. One of the guests at the dinner, Mr. Alfred L. Jones, has offered £400 to start a school in Liverpool for the study of malaria.—The Lord Mayor and members of the city council were present in state at St. Michael's Church on Sunday, Nov. 20th, when a sermon was preached by the Dean of Norwich on behalf of the Royal Southern Hospital. The collection amounted to £121 18*s.* 5*d.* The committee contemplate the expenditure of £3000 on new boilersand machinery and additional bed-room accommodation for the staff.

Pathological Diagnosis Society.

Professor Boyce and Dr. W. B. Warrington entertained the members of the Pathological Diagnosis Society at a conversazione in the Thompson-Yates Laboratories on Nov. 2nd. The reunion was suggested by the transference of the work of the society from Ashton Hall to new premises in the Thompson-Yates Laboratories, where a spacious room has been fully equipped for carrying on the research work of the society. During the past six months Professor Boyce and his assistants have examined and reported upon 398 morbid specimens, sputa, &c., which work has been of incalculable benefit to busy practitioners who have not the time and means at their disposal to make the examinations themselves. The membership of the society has now reached 110. The annual subscription has been increased to 10*s.* 6*d.*

University College, Liverpool: Medical Students' Annual Dinner.

The medical students' annual dinner was held on Saturday, Nov. 19th, at the Adelphi Hotel, under the chairmanship of Dr. James Barr, physician to the Royal Infirmary. Upwards of 120 gentlemen sat down to dinner. The proceedings were of the most agreeable and harmonious character, the speeches being short and the merriment great. The annual dinner is looked forward to with much eagerness by both past and present students, the former seizing the occasion for the renewal of old acquaintanceship.

Liverpool Biological Society.

Professor Sherrington, F.R.S., read an interesting paper, with lantern illustrations, before the members of this society in the zoology theatre, University College, on "Adaptation to Function as Exemplified by the Structure of the Arm." Modern men of science were asking how, not why, and were trying to ascertain how, an organ was made for its particular purpose. At first when the great German Helmholz pointed out that the eye *per se* was imperfect as an optical instrument his declaration was considered impious. The lecturer thought that there was nothing impious in it as an attempt to answer how the extraordinary perfection of vision was achieved with the aid of the brain. Professor Sherrington's experiments were devoted to the same question in regard to the human arm. As the result of extensive work in the laboratory he had found that the further one succeeded in unravelling the structure of the arm the more marvellously adapted to its uses one found it to be, and the more multiplied its adaptabilities.

The Children's Convalescent Home, West Kirby.

The applicants for admission to this institution have been so numerous that the committee have decided to erect a new wing at a cost of £5000, of which a great part has already been subscribed. Last year 832 children were admitted, the greater proportion of whom were sent from Liverpool and its suburbs.

Donations to the Chester Infirmary, &c.

The Chester General Infirmary has received £500, and the Parkgate Convalescent Home £30, from the Duke of Westminster, being the proceeds of the fees paid by visitors for admission to Eaton Hall during the past summer.

Nov. 22nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Reception at the Royal College of Surgeons, Edinburgh.

INVITATIONS have just been issued by the President of the Royal College of Surgeons and Mrs. Chiene to an "At Home" in the College on the evening of Friday, Dec. 9th. A similar reception was given at the Royal College of Physicians some years ago and was by many regarded as a more satisfactory kind of entertainment than the annual dinner.

Illness of Professor Struthers.

I regret to say that Sir John Struthers for some months has been on the sick-list although able to move about a little and to attend to some of his public duties. Last summer he started on a tour to Norway, but had no sooner crossed the North Sea than he deemed it desirable to return. He is now quite confined to his house and in the case of a man of his indomitable spirit this means, I fear, that his condition has become worse.

Complimentary Supper to Dr. Muir.

To-morrow, Wednesday, Nov. 23rd, Dr. Robert Muir is to be entertained to supper by the members of the Edinburgh Pathological Club. This complimentary entertainment is on his appointment to the St. Andrews Professorship of Pathology in Dundee and in recognition of his services as secretary to the club for some years.

Glasgow University.

The University Court has agreed to recognise for purposes of graduation in medicine the lectures of Dr. Hugh Galt on Forensic Medicine and Public Health at St. Mungo's College, Glasgow; the lectures of Dr. W. Ernest Thomson on Physiology at Anderson's College Medical School, Glasgow; and the lectures of Dr. Robert A. Fleming on Medicine at the School of Medicine, Edinburgh. Mr. Matthew Arthur and Mr. Alan E. Clapperton have been appointed to represent the Court on the board of managers of the Western Infirmary.

Digitized by Google

Faculty of Physicians and Surgeons, Glasgow.

At the annual meeting of the Fellows held at the beginning of the present month Dr. Hector Clare Cameron was re-elected president; Dr. A. L. Kelly, visitor; Dr. James Finlayson, honorary librarian; and Dr. J. D. Maclaren, treasurer. The Examining Board for the Licence in Dentistry has been reorganised and Mr. H. E. Clark has been appointed one of the examiners. Much interest was exhibited in the appointment of two representatives to the managing board of the Western Infirmary, and after a contest Dr. Archibald Sloan was re-elected and Dr. Bruce Goff was appointed in place of Dr. J. B. Russell, who desired to retire on account of his removal to Edinburgh. Professor Ralph Stockman, M.D., F.R.C.P. Edin., has been admitted a Fellow of the Faculty.

Royal Hospital for Sick Children, Glasgow.

Dr. George S. Middleton has been appointed visiting physician to the hospital in succession to Dr. James Finlayson, who has resigned. Dr. Finlayson has been one of the physicians since the establishment of the hospital and the directors have now elected him honorary consulting physician.

Glasgow University Club, London.

The club gave a very successful dinner party in the Café Royal, Regent-street, on the evening of Nov. 18th. The Very Rev. Principal Storey occupied the chair, and in proposing the toast of "The Club" took occasion to refer to the recent changes instituted in the Scottish Universities by the late Commission. He regarded the present day as the commencement of a new era in University development and insisted upon the necessity for an increase of funds if the new claims now made upon them were to be adequately met. He trusted that the influence of the members would be of value in this direction, and pointed out that it was specially necessary that the University should be able to increase its laboratories, both for the extension of practical teaching and the encouragement of research. The medical members sent a strong contingent, which included Dr. Heron, Dr. Brisbane, Mr. David Donald, Dr. Guthrie Rankin, Dr. C. O. Hawthorne, Dr. C. D. F. Phillips, and Dr. Norman Maclehose.

University of Aberdeen.

The portrait of the Marquis of Huntly, Lord Rector of the University, painted by Mr. J. Coutts Michie, A.R.S.A., and presented by him to the University, has now been received at Marischal College.—An opportunity has been afforded to the lady students of seeing the proposed home at Aberdeen for the women students there.

Aberdeen Hospitals.

Entertainments are to be held on Sundays in the Palace Theatre for the benefit of these institutions.

Nov. 22nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin University Biological Association.

THE opening meeting of the session will be held in Trinity College, when the President, Dr. William S. Haughton, will deliver the inaugural address on the Present Position of the Roentgen Rays in Surgery and Medicine.

Health of Belfast.

The death-rate for the week ended Nov. 12th from all causes was 26·9 and from the principal zymotic diseases 2·4. The number of cases of typhoid fever notified during the same period has been 47, as compared with 72, 98, 125, 149, 151, and 172 for the six previous weeks respectively. These statistics show that the outbreak of typhoid fever is still, fortunately, subsiding. At a meeting of the Public Health Committee, held on Nov. 17th, the estimates of the probable expenditure for the year 1898 were considered and very fully discussed, and it was found necessary to provide for an expenditure greater than that of the present year by several thousand pounds, the house-cleaning department and the new drain-testing scheme, recently passed, contributing the larger portions of the increase. The very long distances to which the house refuse has now to be carted and the increasing difficulty of finding outlets for it—in which connexion the growth of the city will be responsible for great expenditure—point conclusively to the necessity of refuse destructors being provided for the several districts and also to the desirability of the utilisation of the tramway system for the conveyance of this material to places of disposal where it can be rendered innocuous.

The Annual Dinner of the Cork Medical and Surgical Society; Important Pronouncement with regard to the University Question.

The annual dinner of the Cork Medical and Surgical Society took place at the Imperial Hotel, Cork, on Nov. 12th, when the number of members and their guests amounted to over fifty. Amongst the latter were the Mayor of Cork, Mr. Maurice Healy, M.P., Sir Rowland Blennerhassett (President of the Queen's College), Sir John Scott (ex-Mayor of Cork), Mr. M. D. Daly (chairman of the Cork Dispensary Committee), and other prominent citizens. Dr. Edward Magner, president of the society, occupied the chair, and by delegating to others the duty of proposing some of the toasts introduced what proved to be a very successful novelty. Mr. Healy, M.P., proposed the toast of "The Cork School of Medicine," and in doing so delivered an important speech which is likely to have results. He mentioned that when the Local Government Bill was passing through Parliament he had urged that the Cork hospitals, being part of a successful school of medicine, should be treated more generously than the majority of county infirmaries in Ireland, and though he was not as successful as he could desire he was happy to say that some concessions had been granted. He alluded in complimentary terms to the status of the Cork medical profession and said he was aware that the teachers of the Cork School of Medicine kept well abreast with the wonderful progress of medical science. Touching on the education question he said that addressing such an audience he had no desire to deal with the political aspect of that complex problem, though he had no doubt his opinions on the subject were well known; but one thing he would say with the greatest emphasis—and that was that no solution would be acceptable to him which would have for its purpose the destruction of the Cork School of Medicine and the transference to Dublin of the grant of money now given to Cork. If such a contingency should possibly occur he would regard it as a catastrophe, not alone for his own constituency, but for the whole of the south of Ireland. Mr. Healy was listened to with the greatest attention and when he resumed his seat there was enthusiastic applause. There is no doubt that the sentiments expressed by Mr. Healy will, if occasion require, be emphatically endorsed by his constituency and urgently and persistently pressed on the consideration of any Government that may undertake the solution of the Irish University question. Afterwards Dr. Magner proposed the toast of "The President and Professors of the Queen's College." Sir Rowland Blennerhassett, when replying, stated that one of the first universities known to history was practically a medical school, and the ordinances of that university were so excellent that one of the most modern universities, that of Strasburg, practically adopted them in their entirety. Referring to the pleasure with which he had listened to Mr. Healy's speech he said he felt quite sure that not alone he himself but all the professors had but one desire—to make the Queen's College, Cork, as useful as possible to the community in the midst of which they lived. The President of the society then proposed the toast of "Our Guests" and coupled with it the name of the mayor. He referred to the exertions of his Worship when mayor some years ago to settle the dispute between the local profession and the clubs and said the mayor's sympathies were with the medical men of the city. The Mayor, in reply, expressed the gratification it had been to him to be present at the annual dinner of the society each year he had been mayor, and referring to the club fight said he never could understand how it was that the tradesmen of the city, themselves members of trades union associations, could give opposition to the demands of the medical profession, which were moderate and reasonable. In reply to the toast of the "Navy and Army" Colonel Riordan, R.A.M.C., referred to the sympathy of the profession at large in the desire that the status of his brethren should be improved. Brigade-Surgeon Moriarty, M.D. R.U.I., in

Digitized by Google

very felicitous terms proposed the toast of the "South of Ireland Branch of the British Medical Association," and it having been duly honoured a most enjoyable evening came to a conclusion, music and song forming an attractive portion of the programme.

Curious Order issued at the Cork Barracks with Reference to the Attendance of Civilian Practitioners on the Families of Non-Commissioned Officers.

Recently a medical man practising in Cork was requested to see the child of a sergeant of the King's Royal Rifles. On arriving at the barracks he ascertained that the child was under the care of one of the military medical officers, and accordingly sent a message to him requesting him to see the child in order that they might have a consultation with regard to the case. The military medical officer could not be found as he happened to be out of town, and as the civilian practitioner ascertained that the little patient was very seriously ill he considered it desirable to prescribe for the child. He then wrote explaining his connexion with the case and requesting the military medical officer to meet him in consultation on the following morning. The latter replied declining to do so, as the parents had treated him discourteously by not previously intimating to him their desire to have a consultation, and added in very friendly terms that he had no doubt the civilian practitioner had acted entirely in accordance with professional etiquette. Soon afterwards the same civilian practitioner was requested to visit two other children in barracks and found one of them suffering from a severe attack of septicæmia. The parents were very anxious about the condition of the child and pressed the medical man for a diagnosis. He informed them that it was a case of blood-poisoning. The commanding officer, who was much interested in the child, on hearing of the nature of the illness requested the medical man to send him a report and he courteously acceded to his request. Some days afterwards a board, consisting of medical and engineering officers, held an inquiry, but what the result of the inquiry was has not transpired, but it is understood that the question of the child's illness being produced by insanitary surroundings was before them. Whether it was a case of *post hoc, propter hoc* cannot be ascertained, but almost immediately afterwards an order was issued applying to the whole military district of the south of Ireland that in future non-commissioned officers and privates desirous of procuring the services of civilian medical practitioners must intimate the fact to the commanding officers of regiments in order that it might be communicated to the military medical officer on duty. In the interests of military discipline it may be necessary to issue an edict of this kind, but if so why should it not be made to apply equally to the families of commissioned and non-commissioned officers. Is it as true now as in the days of Shakespeare that what is a mere idle word when uttered by an officer is rank blasphemy when coming from a private? It is stated that the quarters in which the child suffering from septicæmia resided were built on ground contiguous to, if not actually on, the site of closets which had probably been erected at a time when little was known of sanitary science. It has been ascertained, too, that former occupants of the same house were attacked by diphtheria.

Outbreak of Diphtheria in Monaghan.

An outbreak of diphtheria, so far not of a very serious nature, has taken place in Monaghan. The medical men are using every effort to stamp out the disease by isolating the cases, and the schools have been closed up to Jan. 14th, 1899.

Outbreak of Fever at Ballymena.

An outbreak of typhoid fever has occurred at a place called Bridge End, Ballymena, and there are now 15 cases in the Fever Hospital, one patient having died. The Local Government Board has instructed their medical inspector, Dr. Clibborn, to hold an inquiry into certain statements made by the matron of the Workhouse Hospital as to the manner in which cases of fever were treated in the hospital.

Nov. 20th.

DIPHTHERIA AT OLDBURY.—At the meeting of the Thornbury Board of Guardians held on Nov. 11th the medical officer of health (Dr. Bond) reported that 11 cases of diphtheria had been notified during the past two weeks, 10 of these cases having occurred at Oldbury.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Operations for Disease of the Stomach.

DISEASES of the stomach have of late occupied the attention of the learned societies. At the Academy of Medicine on Nov. 15th M. Charles Périer showed a woman, aged fifty-three years, from whom one year ago he had removed the whole of the central portion of the stomach together with the centre of the transverse meso-colon for a new growth which was of about the size of the palm of the hand. After the annular excision had been performed the two ends of the stomach were entirely separated the one from the other. They were joined together by a double row of sutures reinforced externally by a strip of omentum. The colon was found to be enormously distended with fæces, and M. Périer and his assistants were able to manipulate these into the sigmoid flexure and thence into the rectum. Three days afterwards all this mass was removed by means of injections. As long as the mass remained in the intestine the state of the patient was very grave, but after the bowel had been cleared out her state improved and the improvement was continued uninterruptedly until she had completely recovered. M. Périer lays great stress upon this, for he considers that similar retention of fæcal matter is in great measure to blame for the want of success which has hitherto attended gastro-enterostomy and that a favourable result should certainly be brought about if the intestine be emptied in this way. At the present time the patient's appetite is good and digestion is easily performed. Her weight has gone up 15 kilos. since the operation and within the last month she gained 1 kilo. No tumour whatever can be felt in the abdomen and great attention is paid to keeping the bowels regularly open.—At the meeting of the Society of Surgery held on Nov. 9th M. Terrier reported that he had performed jejunostomy for a very extensive case of cancer of the stomach where resection and gastro-enterostomy were out of the question. The patient was now being fed by the intestinal fistula. The operation, however, is only practicable in very few cases. M. Terrier followed the operative technique laid down by Sursnay—an operation which he has performed twice. It is the best operation of a palliative kind, not difficult, and often prolongs the life of the patient.

The Organisation of the Medical Congress of 1900.

The Organising Committee, with Professor Lannelongue in the chair, held a sitting on Nov. 5th at the Academy of Medicine and has definitely settled arrangements for the congress which will open on August 2nd, 1900, and close on the 9th. The entrance fee, amounting to 25 francs, can either be sent to the general manager at Paris or to the committees who are acting in foreign countries. Every subscriber will receive a document showing the extent and arrangement of the section in which he is interested. The congress is divided into five sections: A. Biology: (1) anatomy, descriptive and comparative; (2) histology, embryology, teratology; (3) physiology, physical and biological chemistry; and (4) anthropology. B. Medicine: (1) general and experimental pathology; (2) bacteriology and parasitology; (3) pathological anatomy; (4) visceral pathology; (5) medical diseases of children; (6) therapeutics and pharmacology; (7) nervous diseases; (8) mental diseases; and (9) dermatology and syphilology. C. Surgery: (1) general surgery; (2) surgical diseases of children; (3) surgery of the urinary organs; (4) ophthalmology; (5) laryngology and rhinology; and (6) otology. D. Obstetrics and Gynæcology. E. State Medicine: (1) hygiene, sanitary medicine, and epidemiology; (2) forensic medicine; and (3) military medicine and surgery, naval medicine and surgery, and colonial medicine. Two general meetings will be held, the one on the opening day of the congress and the other at the end. Only those members nominated and invited by the committee will be able to read papers. All proposals relative to the work of the congress must be handed in to the committee before May 1st, 1900. The committee will decide upon these and reserve to themselves the right of examining into their claims. No communication must

Digitized by Google

exceed fifteen minutes in length and speakers in the discussions must not exceed five minutes. The text of the papers or communications or discussions must be given in the same day to the secretary of every section. French is the official language of the congress, but English and German may be also employed in the general meetings and in the sectional meetings.

Hysterical Gastralgia.

At a meeting of the French Electro-therapeutical Society, held in Paris on Nov. 17th, Dr. Apostoli and his assistant, M. Planet, made a communication relative to a case of severe hysterical gastralgia of ten years' standing. It had been suspected to be of tabetic origin but disappeared under treatment by static electricity (*franklinisation*). Static electricity supplies a valuable means of differential diagnosis between hysterical gastralgia and the gastralgia which is an early symptom of incipient tabes. It very quickly detects hysterical conditions by demonstrating peripheral perversions of sensibility, and when applied sufficiently long it has a beneficial effect on hysterical gastralgia.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Vaccination.

THE Senator Dr. Giulio Bizzozzero (whose work in the histology of the circulation won him an honoured name in medical science and led to his appointment to the chair of Pathology in the University of Turin) was the principal speaker at the last meeting of the Turinese Society of Practical Medicine convened in the Policlinico of that city to discuss the all-important question of vaccination and the duties which it imposes on State and citizen alike. Mournful to relate, Italy has, this time for the worse, been influenced by the example of England to relax her faith in the grand Jennerian prophylactic, and at the instance of a man of whom better things were expected, Professor Carlo Ruata of the University of Perugia, to deny the State the right of making vaccination obligatory, on the grounds (mainly) that isolation suffices to keep small-pox at bay, without entrenching on the liberty of the subject. Professor Bizzozzero began by observing that we cannot now as erewhile believe that vaccination can give a life-long immunity from small-pox. If we reflect that out of 1000 vaccinated persons 910 or 920 after eight or ten years are once more accessible to revaccination, there is manifest proof that the immunity is not for life. Proceeding to answer the question, "Are there in Europe nations which are really well-vaccinated?" he remarked that in England vaccination being entrusted to Poor-law guardians (who are not medical men) is carried out by them according to their lights, while revaccination is not obligatory. France, Belgium, and Spain have not obligatory vaccination. On the other hand, Germany stands alone in fulfilling in great measure the demands of hygiene, having in consequence of the calamitous small-pox epidemic of 1870–71 enacted the law of 1874 which "makes vaccination obligatory in the first year of life and revaccination also obligatory at the tenth year." What was the result? With a population of 50,000,000, having in 1871 lost 143,000 lives by small-pox, she found by her law of 1874 the mortality diminished so rapidly that to-day the disease numbers only 116 victims a year. These cases, moreover, occur almost exclusively in towns on her frontier. If it were true, continued Professor Bizzozzero, that a good vaccination does not protect from small-pox we ought to find in small-pox epidemics that the disease diffuses itself in the well-vaccinated no less than in the non-vaccinated countries. But it is not so. In 1870–71, during the Franco-German war, the two peoples interpenetrated each other, the German having its civil population vaccinated optionally but its army completely revaccinated, while the French (population and army alike) were vaccinated perfunctorily. Both were attacked by small-pox; but the French army numbered 23,000 deaths by it, while the German army had only 278; and in the same tent, breathing the same air, the French wounded were heavily visited by the disease while the German wounded, having been revaccinated, had not a single case. These figures made a profound impression on Professor Bizzozzero's audience, as well they might. Coming to Italy, the anti-vaccinationists assert that the country is well vaccinated; and yet, in spite of that, in 1887 there were 17,000 deaths from small-pox, the majority of them infants in whom immunity ought to be at its best. In reality, however (continued Professor Bizzozzero), Italy was always an ill-vaccinated country, revaccination not being obligatory as it is in Germany. Moreover, it has been demonstrated that of the children vaccinated only one-third are in their first year; no wonder, then, if the two-thirds not vaccinated till after that year contribute to swell the death-rate. Again, the anti-vaccinationists contend that obligatory revaccination as in Germany has not wrought the well-nigh complete disappearance of small-pox, but the decree of 1883 as to isolation of the small-pox patient, together with the relative disinfection. They forget, rejoins Professor Bizzozzero, that that decree is in force only in Prussia, and that in the other German countries it is not in force at all, while in these, thanks to obligatory revaccination only, small-pox is well-nigh unknown. In conclusion he said: "Our own experience reinforces that of other countries in placing beyond doubt the efficacy of vaccination when not disjoined from revaccination. Let us then persevere in the struggle for a cause so sacred!" The meeting was all but unanimous in approving Professor Bizzozzero's address; while the anti-vaccinationist minority was but poorly represented and its familiar arguments had all been anticipated and refuted. Dr. Belfanti, director of the Istituto Sieroterapico of Milan, gave evidence as to the inefficacy of isolation supplemented by disinfection, and proved that revaccination had well-nigh stamped out small-pox in the Lombard capital. Dr. Ramello, director of the Municipal Office of Hygiene (Turin), contributed a most instructive history of vaccination in Piedmont from 1805 as a conclusive demonstration of the efficacy of vaccination followed by revaccination, and his facts and figures were supplemented by Professor Pagliani of the Direzione della Sanità Pubblica, showing analogous experience during the last decennium. The meeting shortly afterwards rose, having voted unanimously the following order of the day: "The Society of Practical Medicine considering: (1) that vaccination and revaccination are the only available and effective means of preventing the diffusion of small-pox; (2) that these operations present not the slightest danger when performed *secundum artem*; (3) that not only do they not present any danger during an epidemic of small-pox, but are the only means of arresting such epidemic; (4) that small-pox is almost unknown in countries practising regularly vaccination and revaccination; (5) that therefore this disease ought entirely to disappear from civilised countries; and (6) that we have in animal vaccine a pure source of vaccine which gives absolute security, and can meet every eventuality—resolves that the Istituto Vaccigeno of the State be reopened, while also keeping open those other institutes which guarantee the good preparation of vaccine; and that, by the best means possible, there should be promoted the most effective carrying out of the legislative arrangements now existing concerning vaccination, revaccination, and animal vaccine."

Honour to a Medical Man.

The Senate has just been reinforced by a considerable number of new members, all of them more or less distinguished in public or professional life. General satisfaction is expressed at the elevation to the Upper House of Dr. Enrico De Renzi whose work on the serotherapy of pneumonia[1] is the last of a long series of original and practical contributions to clinical medicine. Born in 1839 in Campania, Dr. De Renzi graduated after a brilliant course of study in the Neapolitan school, and while still a very young man competed successfully with formidable rivals for the Chair of Practice of Physic in the University of Genoa. He shared in the patriotic movement which resulted in Italy's unity and independence and served on the medical staff under Garibaldi in more than one campaign. In 1884 he did useful and intrepid work in the calamitous cholera epidemic in Naples, having previously distinguished himself in tracing the cause and effecting the cure of the strange form of anæmia which proved so fatal to the workmen employed in tunnelling the St. Gothard. Recalled to his *alma mater* to fill the Chair of Clinical

[1] THE LANCET, Oct. 22nd, 1898, p. 1075.

Digitized by Google

Medicine and to act as supplementary professor of pathology, he wrote his well-known treatise on Cirrhosis of the Liver, and has of late been actively engaged in the study of thoracic ailments, chiefly with a view to their treatment by sero-therapeutic methods. He sat in Parliament for the constituency of Avellino, having been elected in 1888, and was for years one of the most useful members in the promotion of public hygiene and in the legislation directed towards the reafforesting of Italy.

Nov. 20th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

The Medical Report on the British Troops in 1897.

CONSIDERABLE sanitary improvements have taken place in the barracks and hospitals, for it is only during the last few years that intelligent interest has been aroused in the drinking supply of the troops. For the first thirteen years of the British occupation the water from the lavatories and laundries of Kasr-el-Nil barracks was allowed to drain into the Nile just above the intake of the water company of Cairo. But now for three years percolating cesspits have been provided and are found to work very well, even when the Nile and the subsoil water are at their highest. The level of the Kasr-el-Nil barrack square has been raised 2 ft., well above the annual infiltration level, and now it is no longer necessary to send the regiment quartered in those barracks into the desert during the months of September and October. At Abbasiyeh a comprehensive drainage system has been laid down and it works well. Last year's figures show that the sanitary reforms are already bearing fruit. The average of sick during 1897 in all Egypt was 54 per 1000, as compared with 63, which was the figure in the two previous years. The actual number of admissions to hospital was 3242, out of an average annual strength of 4449. The death-rate of Cairo alone was 8 per mille less than in 1896. The chief sickness of the year occurred in a regiment which came direct from Malta to Alexandria and had many cases of Mediterranean fever. The highest figures for sick troops occurred, as usual, among young men at the ages of from twenty to twenty-five years. There were 3 cases of small-pox, 1 of scarlet fever, and 6 of diphtheria. 520 cases were returned as "simple continued fever," a term covering many cases of Mediterranean fever and perhaps a few of mild enteric fever. Of the 30 cases of enteric fever 8 patients died; this very high ratio is probably due to the fact that many of the men do not report themselves sick until the disease is far advanced. In 1896 there were 50 cases returned as "enteric" and 10 deaths. It is almost impossible to decide for certain where the soldier gets his typhoid fever, but everyone agrees that it is generally out of barracks. However, the principal medical officer draws attention to the fact that 4 cases occurred among the Royal Engineers all quartered in one portion of the barracks and all admitted to hospital within a period of four days. This certainly seems suggestive of some temporary contamination of the local drinking-supply. Nearly all the cases of enteric fever during the twelve months occurred in men who had been less than one year in Egypt. The enteric fever cases included 2 officers, 1 child, and 1 sergeant's wife. There were 66 cases of dysentery but only 2 deaths. Four officers died and 7 were invalided. The women furnished 266 admissions (51 being normal confinements) and 5 deaths out of an average strength of 216. The children's figures were: average strength, 375; admissions, 618; and deaths, 26, of which 12 were entered as due to dentition or diarrhœa.

The Nile Expedition, 1898.

I have been favoured with copies of the printed advice as regards sanitation issued to all commanding officers and medical officers of the force. The latter were all furnished in addition with "Notes on Medical Services in War" by Colonel Macnamara, R.A.M.C. Special advice is given about drinking water and the advantages of the Pasteur filter, one of which was provided for each unit, were very clearly recognised. Colonels were reminded that a good deal can be done towards training men to abstain from drinking or to drink only small quantities while actually on the march. It is well known that the tyro from sheer nervousness empties his water-bottle in the desert within the first hour of leaving the Nile bank. The hints as regards personal cleanliness include special counsel with regard to care of the eyes. Instructions are given to disinfect beds, stretchers, and railway-carriages which have been fouled by cases of dysentery or enteric fever. Lord Wolseley is quoted as writing that during a campaign provision should be made for twice the ordinary sick-rate of soldiers in the country. This would be about 8 per cent., and to this must be added 6 per cent. of wounded after a severe action. Every medical officer is recommended to have for use in action a strong clasp-knife, morphia solution for hypodermic injection, tabloids of various medicines, antiseptic dressings, and brandy. His orderly should carry more brandy, milk, and beef-tea.

The Quarantine Board.

Dr. Armand Ruffer will leave Alexandria to-morrow to join Professor Fraser of Edinburgh and Professor Wright of Netley as the third member of the Plague Commission. He was specially applied for by the Indian Government a month ago, but it seemed at first impossible to spare him because there was no one on the Quarantine Board qualified to act as president during his absence of six months. Eventually the difficulty was overcome by Dr. Ruffer resigning and by Captain Garner, R.A.M.C., being lent for the time being by the Sanitary Department. When the Commission has finished its labours Captain Garner will resign and Dr. Ruffer will be re-elected.

The Cigarette Trade.

In the early days of the British occupation about 80,000,000 cigarettes were exported from Egypt every week, but now this number is more than doubled. About 65 per cent. are despatched to British possessions, 30 per cent. to Germany, and the remainder to various countries. The great number sent to Germany is due to the fact that German custom-house rules are much less stringent than are custom-house regulations in England. Therefore manufacturers here send their goods to America and elsewhere by preference through agents in Germany instead of sending the cigarettes to London.

Cairo, Nov. 14th.

Obituary.

WILLIAM SMITH, M.R.C.S. ENG., J.P.

ON Nov. 21st, at the ripe age of eighty years, Mr. Smith passed quietly away after some months' illness due to prostatic and bladder troubles. Sixty years ago Mr. Smith went to Redditch as assistant to the late Dr. Pratt, and after the death of that gentleman some five years later he succeeded to the practice. Mr. Smith obtained the Licence of the Society of Apothecaries of London in 1840, and became a Member of the Royal College of Surgeons of England in 1841. Of active and energetic habits, he soon identified himself with the progress of the place, and when the volunteer company was started he became the honorary surgeon to the corps. In all local public improvements he was a prominent factor, bringing to bear clear judgment and sound common-sense into the undertakings with which he was connected. In 1862, when Redditch was made the centre of a petty sessional division, he was the first magistrate appointed, the duties of which office he fulfilled with exemplary diligence up to within the past few months. A colour in political life being almost necessary amid so much public work, Mr. Smith always avowed himself as a Liberal, though not taking a very active part in demonstrations of this kind. Genial in manner, kind-hearted and sympathetic to his patients, Mr. Smith spent an honourable and useful life among the many who esteemed his virtues and valued his friendship. He leaves a name and a personality which will be long regarded with affection and happy memory.

WALTER EDWARD HACON, M.R.C.S. ENG., L.R.C.P. LOND.

MR. WALTER EDWARD HACON of Christchurch, New Zealand, died suddenly on Sept. 20th, at the age of forty-seven years. He was unwell on Sept. 19th, but no anxiety

Digitized by Google

was felt until the following day, when Dr. Mickle, Dr. Stewart, and Dr. Anderson were called in, but unfortunately nothing could be done to avert the fatal issue. Mr. Hacon, himself the son of a medical man, studied medicine at Guy's Hospital and became qualified in 1872 as M.R.C.S. Eng. and L.R.C.P. Lond., after which he held an appointment at Warwick Asylum. Arriving in New Zealand in 1879 he acted as surgeon to the armed constabulary on the west coast of the North Island for one year, and was then appointed resident medical officer in charge of the Sunnyside Asylum, which office he held until 1887, when he took up private practice in Christchurch. While at the asylum he distributed throughout New Zealand a large quantity of vaccine lymph obtained from calves inoculated by himself. Mr. Hacon was the founder of the Canterbury Branch of the St. John Ambulance Association and was also a member of the Christchurch Savage Club. He has left a widow and three young children, for whom much sympathy is felt.

DEATH OF AN EMINENT FOREIGN MEDICAL MAN.—The death is announced of Dr. Konstantine P. Delijiannis, Professor of Pathology in the University of Athens. He studied in Vienna, Würzburg, Berlin, and Paris, where he worked under Pasteur. After his return to his native country he was appointed Extraordinary Professor, and he established a special laboratory in Athens, and in 1882, when an epidemic of enteric fever broke out, he was able to trace its origin to the water-supply, in which he discovered typhoid bacilli. He was delegated to attend various medical congresses in Germany, Belgium, and France, and was a frequent contributor to Greek medical literature on pathological topics. Shortly before his death, too, he published a paper in French on Diseases of the Blood. Besides his medical work he took an active part in promoting general education amongst his countrymen. The cause of his lamented death is said to have been septicæmia.

DIPHTHERIA IN LONDON. — The amount of diphtheria in the county of London in the four weeks ended Nov. 5th shows an increase over that in the same period ended on Oct. 8th. In the like period ended Sept. 10th only 699 notifications came to hand, in the succeeding period the total reached 1039, or 260 as a weekly average, and in the four weeks to Nov. 5th there were recorded 1087 notifications, or 272 as a weekly average. In the October period 2 sanitary districts escaped attack, as against 1 in the November period, but while in the earlier period 5 districts had each 50 attacks or more, with an aggregate of 346, there were 7 such districts in the later period, with an aggregate of 507 attacks. But as a set off against this latter figure other 7 invaded areas had only 10 cases in all. In the earlier four weeks the registered deaths were 125 or 31 weekly, with a minimum of 29 and a maximum of 34; whereas during the later period the total was 145, or 36 weekly, 30 being the minimum and 46 the maximum. The case mortality of 12·0 per cent. in the October period was succeeded by a rate of 13·3 per cent. In the Outer Circle the aggregate of 50 registered deaths gave place to 51 in the respective periods.

THE NATIONAL DENTAL HOSPITAL AND COLLEGE.—The annual dinner of the staff and students took place at the Holborn Restaurant on Nov. 18th, Professor Francis Gotch, F.R.S., occupying the chair, and there was a large attendance of past and present students. Amongst the visitors were Mr. C. S. Tomes, F.R.S., Mr. J. Smith Turner, Mr. Raymond Johnson, Dr. Pasteur, Dr. Dudley Buxton, Dr. H. R. Spencer and Professor J. Rose Bradford, F.R.S. The chairman, in proposing the toast of "The Hospital and School," criticised the modern methods of examinations and claimed that at all events the teachers should be represented on the Examining Boards. In respect of the dental curriculum he thought that some of the general anatomy and physiology now required might well give place to some pathology and bacteriology. From his former experience as Dean of the Medical Faculty at Liverpool he was able to speak in high terms of the good qualities of the modern dental student and he thought that an effort should be made to secure a degree in dental surgery at the new University of London. Amongst other items in an excellent programme a song by Mr. Alfred Smith with violin *obbligato* by Mr. E. W. Roughton and the recitations by Mr. Frank Braine, were much appreciated.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE programme of the General Medical Council has seldom been loaded with more numerous or weighty questions than on the present occasion. We enumerated a few of these last week, but hardly any of them have been discussed as yet. The Council is deeply engaged in the consideration of penal cases. Several applications for restoration to the Register have been disposed of. Unless care is taken to save time there is a prospect of a somewhat prolonged session.

The address of the President shows that he does not allow the distance between Edinburgh and London to interfere with his attention to the duties of his high office. The account of his communications with the Lord President of the Privy Council as to the practicability of obtaining an amendment of the Medical Act such as would prevent "de registered" persons from flaunting all their titles and practising as though nothing had happened and of his communication with the Home Office on the subject of informal death certification is satisfactory. The answers of the Lord President on the former subject are significant and should be well considered by those who talk glibly about amendments of the Medical Act as though we had only to wish for them to have them accomplished.

The first letter of Sir Charles Lennox Peel, the clerk to the Privy Council, on this subject was published in the minutes of the Executive Committee on July 12th. In this he says he is desired by the Lord President to say that he cannot hold out any hope of legislation being undertaken to effect an amendment of one provision of the Act of 1858, even if the degree-giving bodies had expressed a desire for the amendment, which, added the Duke of Devonshire, "does not appear to be the case." His Grace appears to think that the degree-giving bodies are not anxious for an increase of their powers of dealing with graduates who discredit their profession and their university. But there has lately been a great development of feeling on the part of the universities on this subject and there is little doubt that Sir William Turner will be able to correct this impression. Sir William Turner is an important representative of the Scottish universities and of one in particular which was the latest to see the necessity for such additional powers of discipline as are asked for by the General Medical Council. Happily now there is reason to believe that all the universities are of the same mind in wishing for amendment, and at the Executive Committee on Monday last Sir William Turner was requested to get from them and from other qualifying bodies also an expression of their wishes on the subject. We shall be disappointed if the result of Sir William Turner's inquiries is not to evoke such a reply as to leave the Lord President in no doubt that in promoting the amendment sought for by the General Medical Council he would be complying with the views of the universities and corporations alike. It is not conceivable that the universities which now vie with the corporations in qualifying men for the medical profession would be permanently opposed to such a reasonable change in the law, one which will tend to secure in the public interest a high standard of professional conduct.

Remarkable testimony to the stringency of the examinations of the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons

Digitized by Google

of England was forthcoming during Tuesday's sitting. From certain tables supplied by the Medical Department of the Royal Navy (which still require verification), by the Director-General of the Army Medical Service, and by the Under Secretary of State for India, it appeared that, whereas there had been a very high percentage of rejections among candidates for commissions in the services holding the degrees of the Universities of Edinburgh, Aberdeen, Glasgow and Dublin, the diplomas of the Irish and Scottish Conjoint Boards, and the Licence of the Society of Apothecaries of London, out of 39 candidates holding the diploma of the English Conjoint Board 32 had obtained commissions by competitive examination. The success of the English students impelled Dr. McVail to propose that the Examination Committee of the Council should be asked to report upon the tables—a motion which, in our opinion, was rightly rejected, for it reflected unjustly upon the examiners for the commissions in the services and at the same time sought an explanation where no explanation is needed. The examinations of the English Conjoint Board are very thorough and the men who hold their diplomas are—everyone knows it—as highly educated as the graduates of many universities and in some directions more practically equipped. Dr. McVail by his motion called marked attention to the unfair position in which, as yet, the London student is placed in being unable to obtain an M.D. degree at the conclusion of studies severe enough to procure him the distinction elsewhere.

Most of the short sitting of Tuesday afternoon was occupied in discussing Mr. Horsley's resolutions asking for the production of all documents in relation to certain cases in which unregistered persons had been prosecuted by the Council, and a similar resolution of Mr. Brown in regard to the case of the late Mr. H. Kingsley Hunter. The Council by large majorities and with little dissent passed resolutions showing that it has no real objection to the inspection of such documents under conditions securing their preservation in such order as may make them available for easy reference. The members of the Council will thus have the opportunity of seeing documents which cannot but be instructive. It is to be hoped that they will share with Mr. Horsley the study of them. There are too many proofs that either the system of conducting prosecutions at present adopted is faulty or that the law is inefficient. If this latter supposition be the correct one the occasion is good and the time is ripe for asking the Government for amendments despite the views of the Privy Council. Within the last few weeks a prosecution against an unregistered person has ignominiously failed in Scotland before the High Court of Justiciary, more, as we read the deliverances of the judges, from faulty presentation of the case than from any merits in the defendant. If the inspection of documents will throw light on such failures it will confer a very great service on the public and the medical profession.

On Wednesday the Council sat much of the day *in camerâ*, while on Thursday they commenced the investigation of the penal cases.

In connexion with the meeting of the General Medical Council we are glad to be able to state—and the members of the Council as well as other members of our profession will be pleased to hear—that the health of Mr. W. J. C. Miller B.A., who was for so many years registrar of that body, is very satisfactory. Writing to a friend he states that what he now suffers chiefly from is a great difficulty with his handwriting and slight weakness in walking. It will be remembered that Mr. Miller was obliged to resign the duties which he had so long and so faithfully and ably discharged owing to a sudden breakdown in his health. He would like his old friends to know that he now lives with his sister in a very pleasant house; he is often heard to say that the lines have fallen unto him in pleasant places.

TUESDAY, NOV. 22ND.

The session of the General Council of Medical Education and Registration was opened to-day in the offices of the Council, Oxford-street, London. Sir WILLIAM TURNER, President of the Council, occupied the chair and there was a full attendance of members.

The President's Address.

The PRESIDENT, in accordance with custom, opened the proceedings with an address. He said:—

"It is not my intention to trespass on your time and attention by the delivery of a lengthy address. It may, however, be useful to refer to some of the subjects to which the Council will require to give consideration during the present session. In the first place I may call to your recollection that during the session held in May I, as your President, was asked to put myself into communication with some of the Government departments regarding questions in which the Council and the medical profession are greatly interested. The disciplinary powers exercised by the Council and the licensing bodies have frequently been under the consideration of the Council and the Executive Committee, and at the May meeting of Council I was requested to communicate with the Lord President of the Privy Council as to the practicability of obtaining such an amendment of the law as would effectually prevent the holder of a medical diploma or degree from using the title thereof after his name had been erased from the Medical Register under Section 29 of the Medical Act, 1858, and for so long as the erasure continued in force. The Council will find in the minutes of the Executive Committee, July 12th, 1898, a print of the letter which I wrote to the President and of his reply. Subsequent to this correspondence I was requested by the Executive Committee to ask an interview with the Clerk of the Privy Council with reference to this matter. As I thought that it would facilitate the consideration of the subject if I could place in the hands of the Privy Council some definite proposal as to the direction which legislation should take I requested Mr. Muir Mackenzie to draft clauses which might be embodied in a Bill. This was accordingly done and at an interview with Mr. Almeric Fitzroy, who has succeeded Sir Charles Lennox Peel in the office of Clerk to the Privy Council, I explained the purport of these clauses and left a copy with him. The subject will, I was assured, receive due consideration. I was given to understand that as a preliminary step it will be necessary to ascertain if the universities would offer no opposition to the Medical Act, 1858, being amended, so that if a graduate in medicine had his name erased from the Medical Register, under Section 29 of this Act, his right to use the title or titles obtained from his university should be suspended so long as the erasure remained in force. At the meeting of the Executive Committee yesterday I was requested to continue in communication with the Privy Council and also to ascertain the opinion of the medical licensing authorities on the question of suspension of the right to use a title or titles so long as the erasure of a name and title remains in force. The subject of death certification and the amendment of the law regarding it has frequently been before the Council, and a strong opinion has been expressed that the law required alteration, so that the irregularities, which now only too frequently occur, should be in the future no longer possible. At the request of the Executive Committee I put myself into communication with the Home Department on this subject, and requested Dr. Church to accompany me to an interview with the Permanent Under-Secretary. The whole question was discussed at our meeting at considerable length, and the evils which exist were fully recognised by the Under-Secretary. We were assured that the matter had been for some time under consideration, with a view to an amendment of the law, and that a communication would be made by the Home Office to the Local Government Board on the subject. In the month of May the Council appointed a committee,

Digitized by Google

consisting of Mr. Tomes, Mr. Horsley, and myself, to take steps to induce the Government to insert a clause in the Companies' Act Amendment Bill with the object of preventing the registration of companies to carry on medical, surgical, and dental practices. A meeting of the committee, at which Mr. Muir Mackenzie was present, was held early in October, when a discussion took place as to the best means to carry out the instruction of the Council. It was arranged that clauses should be drafted by Mr. Muir Mackenzie and placed in the hands of the Lord Chancellor. This has accordingly been done. It is due to Mr. Tomes to state that he has taken an active and important part in bringing the whole of this question before the notice of the Lord Chancellor. In connexion with the resolution of the Council, which remitted to the Executive Committee to take steps to secure that the Medical Council shall receive due recognition and representation in national functions and ceremonies, a sub-committee, consisting of Sir Dyce Duckworth, Mr. Carter, and myself, was appointed to obtain the necessary information. So far as our inquiries have gone we have not received much encouragement and we have been told that, as regards recognition and representation in national functions and ceremonies, no corporate body has any vested right of participation. In any public ceremony the director of the function considers applications to participate, and grants them as far as he is able, or he may issue invitations at his own discretion, but there are no rights or privileges in relation to the matter. At our meeting in May a committee, consisting of Sir Richard Thorne, Dr. Glover, Dr. MacAlister, and Sir Christopher Nixon, was appointed to confer with delegates from the committee which had framed the Midwives' Bill and to report to the Council. The conference was held on June 25th, 1898, and the report of the proceedings has been circulated amongst the members of the Council. I thought it advisable to authorise its circulation so that members should have ample time to read and consider what took place at the conference before the Council enters on the consideration of the report which our committee is to present on the subject. The Council will, I am sure, hear with much satisfaction that of the first impression of 20,000 copies of the British Pharmacopœia issued in the spring of the year all the copies have been sold. After consultation with Dr. Leech, chairman of the Pharmacopœia Committee, in the month of October 1500 additional copies were ordered to be printed to meet immediate necessities, and of these 500 have been sold. Dr. Leech and his committee will, I have no doubt, during the present session advise us as to the future. The Executive Committee will submit for your consideration a revision of the memorandum on reciprocity of medical practice in relation to foreign countries so far as it affects the question of the conditions under which foreign medical practitioners are allowed to practise medicine in the United Kingdom. The treasurers will present a report on the proposed alterations on our building and another on a proposed sinking fund to meet the charge for the alterations which have been made on our property. You will also have to take into consideration, on a report from the Examination Committee, the inspector's report on the examinations of the Apothecaries' Hall of Dublin held during the spring and summer. In this connexion I have to state that, owing to Dr. Sidney Coupland having accepted the appointment of a Commissioner in Lunacy, he has found it necessary to resign his position as our inspector. Whilst congratulating Dr. Coupland on his appointment to the responsible office for which he has been selected the Council will, I am sure, join with me in expressing regret that we are no longer to have the benefit of his valuable services. In conclusion, I have to state that, under the instructions of the Penal Cases Committee, several charges made against registered practitioners will have to be investigated. The Council will, I feel sure, give to these cases the thoughtful care and attention which are essential when questions affecting the character and conduct of members of our profession are being inquired into."

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, the Council thanked the President for his address and requested him to allow it to be printed in the minutes.

Examinations for the Services.

The first business on the programme was to receive three tables, one showing the results of the competition held on Oct. 31st for commissions in the Medical Department of the Royal Navy; the second showing the results of a competition held in August for commissions in the Royal Army Medical Corps; and the third showing the results of a competition held in August for commissions in the Indian Medical Service.

Mr. ALLEN (Registrar) said he must ask that the first table, that referring to the Navy, be withdrawn because some of the figures in it would require to be verified.

On the motion of Dr. P. HERON WATSON, seconded by Sir RICHARD THORNE, the Council received the second and third tables and thanked for them respectively the Director-General and the Under Secretary of State for India.

Dr. MCVAIL said he wished to call attention to a somewhat extraordinary state of things disclosed by the tables. Taking the three tables he found that there were 39 candidates from the English Conjoint Board and all got commissions excepting 7. From the Irish Conjoint Board there were 7 candidates and 4 got commissions; from the Scottish Conjoint Board 5 candidates and only 2 got commissions; from the University of Edinburgh, 13 candidates and 6 commissions; from the University of Glasgow, 4 candidates and 3 commissions; from the University of Aberdeen, 3 candidates and 3 commissions; from the University of Dublin, 5 candidates and 2 commissions; and from the Apothecaries' Society of London, 4 candidates and 2 commissions. Though the others were fairly comparable there was an extraordinary difference between them all and the Conjoint Board in England. The matter was a serious one and he moved that the tables be remitted to the Examination Committee for report.

Mr. BROWN, seconding the motion, said that this apparently wholesale rejection of candidates should be inquired into.

Sir DYCE DUCKWORTH said that Dr. McVail should indicate in his motion what it was that he desired the Examination Committee to inquire into. For eight years he had been an examiner in medicine for the navy and therefore he could speak with some authority so far as the navy examinations were concerned, though he might explain that he was no longer an examiner. In examining a candidate for the navy the examiners knew nothing about the man; he was a mere number to them. They did not know what school he had studied at and the marks were given simply according to the merit displayed in the examination. There was no bias whatever, and indeed he could not conceive a better or more impartial examination. He had no doubt that the same held good with regard to the other services.

Mr. TEALE submitted that the question of the fairness of these examinations lay entirely outside the functions of that Council.

Mr. CARTER said that information as to the particular grinder with whom the candidate had worked would be more useful and to the point than information as to the school from which he had got his diploma.

On a show of hands being invited 11 were held up in favour of the motion and an equal number against it.

The PRESIDENT said it was evident that a considerable number of the members had not taken part in the vote. He had taken occasion before to point out the difficulty of the position when a considerable number of the members present refrained from voting and he would point it out again.

Dr. MCVAIL claimed that the names and numbers be recorded.

Sir RICHARD THORNE asked as a point of order whether members who had refrained from holding up their hands were entitled to vote now when the names and numbers were recorded.

The PRESIDENT said he had noticed on former occasions that members who had not held up their hands responded when the names were taken and there was no Standing Order against such proceeding. It was a question, however, which might very well be considered.

Dr. MACALISTER submitted that the show of hands was not the formal vote.

After some further discussion had taken place the members of the Council expressed a desire to have a ruling from the chair on the point, whereupon the PRESIDENT ruled that when the names were called it was open to members who had not raised their hands to respond and thus record their votes.

The roll being called 13 members voted against the motion, 11 for it, and 5 declined to vote. The motion was accordingly lost.

The Employment of Unqualified Assistants.

A number of communications on this subject were (in accordance with the recommendation of the Executive Committee) referred for consideration and report during the present session to a committee consisting of Dr. Church, Dr. MacAlister, Dr. Bruce, Mr. Bryant, Mr. Brown, and Mr. Teale, the last-mentioned to be chairman.

The Inspection of Documents.

Mr. HORSLEY asked the leave of the Council to consider next in order all notices of motion on the programme relating to the inspection of documents.

Dr. MACALISTER submitted that the notices standing in the name of Mr. Horsley did not comply with the new Standing Order with reference to the inspection of documents in as much as the notices did not specify the purpose for which the inspection was to be made.

Mr. HORSLEY said Dr. MacAlister surely did not suggest that he should put down on the public programme the purpose for which he desired to see the documents.

Dr. GLOVER suggested that Mr. Horsley might give the Council his reasons *in camerâ*.

Mr. HORSLEY said he would have no objection to that course, but as to the notices being in order he had taken legal advice on the subject and he submitted that they were strictly in order.

After some further discussion leave was given to Mr. Horsley as desired.

The first notice of motion stood in the name of Mr. Brown and was to this effect:—

That all minutes, papers, and documents relating to the recent prosecution of the late Mr. H. Kingsley Hunter, Licentiate of the Society of Apothecaries of London, be presented to the Council —

and Mr. BROWN moved accordingly.

Dr. MACALISTER said that there was an appeal pending in this case and that in consequence many of the documents could not be produced, certainly could not be printed, as the motion suggested.

Mr. HORSLEY admitted that there might be a difficulty about printing, but there was no difficulty in the way of a confidential inspection by the members of the Council.

Sir RICHARD THORNE urged Mr. Brown to withdraw his motion on the ground that many of the documents were in other hands.

Mr. BROWN said that wherever the documents might be at the present moment the whole case would have to be gone into very thoroughly because the profession took the very deepest interest in it. He appealed to the Council to give to him and others interested in the matter an opportunity of informing themselves as to all the facts of the case. If the documents could not be printed, then he asked an opportunity for their confidential inspection.

Mr. HORSLEY, seconding Mr. Brown's motion, said with regard to the documents not in the possession of the Council that they were in the hands of the servants of the Council and could be brought here without the slightest inconvenience. He was not aware that the appeal case was even in the list. At the present moment certain of the members of the Council knew all the facts and he saw no reason why they should be in this exceptional position. With all respect he claimed for himself the same privileges as the committee in this matter.

Dr. ATTHILL thought that in view of the appeal case it would not be wise to produce the documents.

Dr. GLOVER said that in his opinion Mr. Horsley was perfectly within his rights in making the claim he did and he supported the motion. Every member of the Council was entitled, he held, to see the material upon which the Penal Committee had acted in the case.

Sir JOHN BATTY TUKE said he felt quite clear on the point that any member of the Council was entitled to see the documents.

Mr. TOMES contended that as the Council and not the Committee was the party to the action no obstacle should be thrown in the way of any member of the Council seeing the documents.

The Council then agreed to the motion in the form that all minutes, papers, and documents, &c., "be produced to the Council," the motion being agreed to by a very large majority.

Mr. HORSLEY moved:—

That all documents in relation to the case of an unregistered person named Hamilton be produced for inspection by members of the Council.

He said that this person had been prosecuted unsuccessfully by the Council and he intended to move a resolution with reference to the case.

Sir CHRISTOPHER NIXON seconded.

The proposal was agreed to.

Mr. HORSLEY next moved:—

That all documents in relation to the case of an unregistered person named Steel be produced for inspection by members of the Council.

Steel, he said, had been successfully prosecuted by the Council, but he wished to raise the question of his conduct since his conviction. He could not do so without seeing the documents in the case.

Mr. BROWN seconded and the motion was also agreed to.

Mr. HORSLEY further moved:—

That all documents in relation to the case of an unregistered person named Allinson be produced for inspection by members of the Council.

He stated that this case was parallel with that of Steel.

Sir CHRISTOPHER NIXON, in seconding, said he would be prepared to second a motion in similar terms from whatever member of Council it came. He had the strongest possible feeling that all the documents belonging to the Council should be open to the individual members of the Council. There should be a Standing Order to the effect.

The motion was agreed to.

The PRESIDENT pointed out that after the adoption of the four resolutions just passed it was essential to arrange that the documents in question should be inspected under conditions such as to ensure the preservation of their privacy. There must be a room in which they could be exhibited, someone must be responsible for them, and hours at which they could be seen must be fixed.

Some conversation ensued, and this resulted in the determination that documents which members wanted to inspect might be seen in the store-room under the Council Chamber, that they might be seen at such times as suited the convenience of those members who wished to inspect them, and that if inspected before or after office hours the superintending clerk should be paid for overtime.

The Council adjourned.

WEDNESDAY, NOV. 23RD.

The Council met again to-day, Sir WILLIAM TURNER being in the chair.

The Case of Charles Alexander Ducket.

The Council proceeded with the consideration of the case of Charles Alexander Ducket, of 74, Brooksby's-walk, Homerton, registered as Mem. R. Coll. Surg. Eng. 1888, Lic. R. Coll. Phys. Lond. 1888, Lic. Soc. Apoth. Lond. 1888, of 12, St. George's-terrace, Great Yarmouth, who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That he, being a registered medical practitioner, caused and permitted an unqualified person named David Moses Roberts to attend and administer medical treatment to patients who required his (Ducket's) services, as if he had been a duly qualified practitioner, and in particular that he (Ducket) caused and permitted the said unqualified person to attend and administer medical treatment to a woman named Louisa White and to an infant named Hilda Helen Bailey in the circumstances stated in the evidence and in the verdicts of the coroner's juries taken and given at inquests held on the deaths of the said deceased. The complaint against him (Ducket) was that in the said matters he had been guilty of infamous conduct in a professional respect. The information and evidence consists of the depositions taken and verdicts given at the said inquests, which have been transmitted by the coroner to the General Medical Council.

Mr. DUCKET attended without legal assistance.

After Mr. MUIR MACKENZIE had read the depositions taken and the verdicts of the juries, Mr. Ducket was asked by the President whether he had anything to say to the Council by way of explanation.

Mr. DUCKET said he had to confess that in the two cases mentioned he had been negligent, and he could only plead that he was a little pressed with work on account of the absence of the principal, Mr. Evans. He denied, however, that he had any design to cover the unqualified assistant. It was Mr. Evans who employed him (Mr. Ducket), and while he was with him he was a very good master and he should not like to suggest that it was in any way at Mr. Evans's instigation that Mr. Roberts attended these cases.

Digitized by Google

The PRESIDENT asked whether he understood Mr. Ducket to admit neglect of the patient in these two cases.

Mr. DUCKET said he admitted that there must have been neglect.

Sir RICHARD THORNE pointed out that there was nothing in the charge as formulated about negligence and asked whether it was competent and go beyond the charge.

Mr. MUIR MACKENZIE said that as long as his experience went back the practice had been ever to consider the neglect of patients, and neglect of patients certainly came within Section 29 of the Medical Act. The charge that was directed by the Penal Cases Committee to be formulated was that of causing and permitting an unqualified person to attend.

Mr. DUCKET, in reply to questions addressed to him by various members of the Council, said that he was assistant to Mr. Evans, and although he acted as substitute for him when he went away this made no difference in his position or salary. In Mr. Evans's absence Mr. Roberts was under his control in a general way and after the first case happened he warned him that he should call in a qualified man. He had no interest in the practice beyond his salary, and after these inquests he was discharged by Mr. Evans. He had no power to dismiss Mr. Roberts nor did he consider himself in any way responsible for what Mr. Roberts did. When he (Mr. Ducket) was engaged Mr. Evans told him that he already had an assistant, but in view of the action of the General Medical Council he required a qualified man and he would keep on the unqualified assistant as a dispenser and collector of rents. It was with this clear understanding that he engaged himself as assistant to Mr. Evans. Though he was on the best of terms with Mr. Evans while in his employment he had not seen him since he left it, nor had Mr. Evans volunteered to come forward and speak for him before this Council. He was quite aware that what he had done had damaged Mr. Evans's practice as it had certainly damaged his (Mr. Ducket's) reputation and he was extremely sorry for what had occurred.

After deliberating *in camerâ* for a time the Council decided that the charge had not been proved to their satisfaction.

Restoration to the Medical Register.

The Council decided to deal with a report in which the Executive Committee stated that they had considered petitions for the restoration of certain names to the Medical Register by medical practitioners whose names had been removed therefrom under Section 29 of the Medical Act, 1858.

The PRESIDENT said that as the report referred to persons who were not present it ought to be taken in private.

Members of the public who were in the hall thereupon withdrew. On their readmission, one hour and a quarter afterwards,

The PRESIDENT said: The Council have considered the report of the Executive Committee on the petitions for the restoration of names to the Medical Register by medical practitioners whose names have been removed therefrom under Section 29 of the Medical Act. As regards William John Patterson the Council decline to restore his name to the Register at present. As regards Robert Ingram Robertson the Council resolve to call the attention of Mr. Robertson to his statement that though unregistered his occupation has been that of a medical practitioner and they refuse his application. As regards Robert Alexander Douglas Lithgow, the Council resolve that his application be refused. As regards Herbert Tibbits the Council resolve that his application be refused. As regards Alfred Freeman the Council resolve that his application be adjourned and that the documents now before the Council be forwarded to the Royal College of Physicians of Edinburgh for its consideration.

Inspection of Documents.

Mr. HORSLEY obtained the leave of the Council to proceed with the two notices of motion which he had placed upon the business programme for the day. The first of the two was—

That all documents in relation to the case of Dr. Farrar be produced for inspection by members of the Council.

He explained that this related to a case of "covering" of great importance, for it contained a point that had not arisen in any previous case. His intention was to draw attention later in the session to the procedure of the Council in considering cases of "covering."

Asked if the case had been before the Council and if it had been adjudicated upon—

Mr. HORSLEY replied that no judgment had been given upon it as it had been withdrawn by the complainants, the Medical Defence Union. The record in the case appeared in the Council's minutes of 1895, pages 61 and 62.

Sir DYCE DUCKWORTH: This name is not on the Register.

Dr. MACALISTER: He is dead.

The PRESIDENT: If the man is dead what can you do with him?

Mr. HORSLEY: I have nothing to do with the case of "covering." It is known that the man is dead and that the unqualified assistant took a public-house shortly after the Council gave their decision. What I want the document for has relation to the extremely important point as to the way in which evidence is laid before us, because I have a distinct resolution relating to that point which I will give notice of at the proper time.

The PRESIDENT: This is a case which death has determined. What object is there in the question of how the evidence has been tendered in the case of a person who is gone past recovery?

Mr. HORSLEY: I have nothing to do with the case itself. I was simply asking for the documents, for I know as a matter of fact that certain evidence was brought before this Council in a certain way and it ought to form a test case in regard to our procedure in cases of "covering." The request for documents has nothing to do with the merits of the case.

Dr. MACALISTER suggested that as all the documents were printed at the time for private circulation it would be easy to provide a copy for inspection.

Sir RICHARD THORNE said he hoped they would pass the motion. When a member asked for documents he ought to get them without opposition. If the Standing Order on the subject passed last session came forward again he would not vote in the way he did then.

The motion was agreed to.

Mr. HORSLEY next moved:

That the lawyer's bill of costs for 1897 be produced for inspection by members of the Council.

Dr. MACALISTER suggested that this had no reference to penal cases.

Mr. HORSLEY said that it related entirely to the penal cases which he wished to cite to the Council. The bill of costs in question related to their legal procedure, especially in regard to "covering" cases. It fell under the notice which he had given to "draw attention to the procedure of the Penal Cases Committee in relation to certain complaints of 'covering' made to the Council."

Mr. BROWN seconded.

Dr. MACALISTER: There are two classes of documents, one relating to penal cases and the other not to penal cases, and this document does not seem to refer to penal cases.

Mr. HORSLEY rose to a point of order. He said that when Dr. MacAlister talked on this subject as he was doing he was calling in question his (Mr. Horsley's) honour. He had informed the Council that he required this document for penal cases in relation to the case which had just been referred to.

Dr. MACALISTER said that that was exactly what it was necessary to bring out.

Mr. HORSLEY retorted that that was exactly what he had brought out already and that it was so was the reason why he had risen to a point of order.

Sir JOHN BATTY TUKE considered that discussion of this kind was to be altogether deprecated because it was calculated to give the public outside an impression that there was something to hide, and there was not.

Sir DYCE DUCKWORTH said that he could not see that any objection could arise to a member of Council seeing bills of costs. His view, as one of the treasurers of the Council, was that it was quite open to any member of the Council to see any particular bills of costs which he might wish to see.

The motion was then agreed to.

Mr. HORSLEY thereupon moved:—

That all the documents relating to the penal cases referred by the Penal Cases Committee to the present session of the Council be produced for inspection by members of the Council.

He remarked that after what had fallen from Dr. MacAlister in connexion with the previous motion he declined to give any reason for making the present proposal.

Dr. MACALISTER said that what was now wanted were distinctly documents relating to penal cases.

Digitized by Google

Mr. BROWN seconded the motion, which was agreed to without further comment.

Midwives' Registration.

On the motion of Dr. MACALISTER, seconded by Dr. BRUCE, a report from the Midwives Bill Conference Committee was received and entered on the minutes.

Tropical Diseases.

Dr. MACALISTER moved the insertion into the minutes of a communication on this subject. The programme showed that the letter in question had reference to the measures adopted by the Government, after requesting the opinions of the General Medical Council and the British medical schools. Its terms were as follows:—

Downing-street,
November 9th, 1898.

SIR,—1. In the fifth paragraph of the letter from this Department of the 11th of March last it was stated that Mr. Secretary Chamberlain, with a view to supplementing the instruction afforded by the medical schools, was endeavouring to make arrangements for giving to colonial medical officers special clinical instruction in tropical medicine such as is given at Netley and Haslar in the case of medical officers of the Army, Navy, and Indian Medical Services, and which, from lack of the necessary material, cannot invariably be given at the medical schools.

2. These arrangements have now been made. The Directors of the Seamen's Hospital at the Albert Docks, which offers exceptional opportunities for studying cases of tropical disease, are providing the necessary buildings and teachers for the accommodation and instruction of the medical officers who may hereafter be selected by the Foreign Office and the Colonial Office for appointments in the tropics. A substantial contribution towards the initial cost of the buildings is being made by the Government, and it is hoped that by the 1st of October, 1899, it will be possible to receive medical officers at the hospital for purposes of instruction.

3. It is proposed that, as is at present the case, candidates for medical appointments in the British colonial possessions shall be fully qualified before they can be put upon the Secretary of State's list, that from this list a certain number shall be selected annually to fill the vacancies which may occur in the Colonial Medical Service, that the selected candidates shall be trained for a period of at least two months at the Seamen's Hospital, and that they shall then be sent to the colonies or protectorates to which they have been allotted, where, when practicable, they will be attached in the first instance to the head quarters hospital for the purpose of gaining additional experience. In estimating the respective merits of candidates on the Secretary of State's list regard will be had to the fact whether or not they have already received instruction in tropical medicine.

4. Judging from the replies which have been received from the General Medical Council and the medical schools, Mr. Chamberlain believes that the above arrangements will prove acceptable.

5. Although the school at the Seamen's Hospital is designed for the training of medical officers for the Government service, doubtless there will be many other medical men, such as the medical officers of missionary societies and trading corporations and private practitioners, who propose to settle in tropical countries, who will be glad to avail themselves of the advantages which such a school can offer.

6. The colonies are being asked to make pecuniary contributions, to collect pathological material for use in the school, and to support the scheme in every possible way. So far, then, as this Department is concerned, no effort is being spared to make the school a success, and Mr. Chamberlain feels confident that the medical schools of this country will also do what is in their power to assist the development of an institution which is likely to be of general service and to benefit medical science not only by giving a stimulus to the investigation of tropical disease, but also by qualifying a body of men to become investigators.

7. Mr. Chamberlain is so impressed with the importance of this subject as affecting the administration and well-being of the tropical colonies that in addition to this scheme for providing a thoroughly efficient colonial medical staff, he wishes to encourage by every means in his power scientific inquiry into the causes of tropical diseases. Accordingly, he has already, after correspondence with the Royal Society, instituted a commission to study the subject of tropical malaria on the following lines.

8. The Royal Society has nominated two competent observers who have already proceeded to Italy for a short preliminary study and will afterwards go to some place in Africa, probably in the first instance to Blantyre, in the British Central Africa Protectorate, where it has been ascertained that there exist good opportunities for carrying out the purpose in view.

9. In addition the Secretary of State has nominated an experienced medical officer of the colonial service to aid in the investigation. This officer will, in the first place, proceed to India in order to study under Surgeon-Major Ronald Ross for about two months so as to make himself acquainted with the result of that gentleman's researches. He will then join the other two observers in Africa, where they will together pursue their studies, which will probably occupy about two years, and report from time to time to a committee in England nominated jointly by the Royal Society and the Secretary of State.

10. Mr. Chamberlain has been glad to learn from the replies which have been sent to the letter referred to above that arrangements already exist, or are about to be made, for giving special instruction in tropical medicine in upwards of twelve British medical schools, and he trusts that these schools, some of which (such as that of University College, Liverpool; University College, Bristol; and the University of Durham College of Medicine at Newcastle-on-Tyne), being situated in large seaports, possess exceptional facilities for the study of tropical disease, will keep in correspondence with the School of Tropical Medicine at the Seamen's Hospital with a view to mutual assistance and advice.

11. In conclusion, Mr. Chamberlain desires to express his thanks to the General Medical Council and the British medical schools for the warm interest which they have taken in this matter, and for the ready and cordial support which they have afforded him. He will welcome any suggestions which may be made in furtherance of the object in view.

I am, Sir, your obedient servant,
EDWARD WINGFIELD.

The President of the General Medical Council.

Sir DYCE DUCKWORTH, in seconding Dr. MacAlister's motion, pointed out that the Colonial Office letter did not commit the Council to anything.

Sir JOHN BATTY TUKE said that it contained an indication that Mr. Chamberlain would welcome any suggestions which might be made by the Council.

Dr. MACALISTER reminded members that anyone could propose a motion on the subject.

The letter was then ordered to be entered on the minutes.

The Council adjourned.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations and having conformed to the by-laws and regulations have been admitted Members of the College:—

Acland, Hugh Thomas Dyke.
Adam, John Law.
Alexander, Kenneth Bush.
Ambrose, William Cole.
Balderston, Robert.
Bates, Thomas Wright.
Berry, Thomas Percival.
Berryman, Edmund Newton.
Blackburn, Vernon Kent.
Bonnet, Saint René.
Brown, James Warburton.
Burd, Cyril Pritchard.
Canman, David.
Carsberg, Alfred Ernest.
Chadborn, Charles Nugent.
Churton, John Gaitskell.
Clayton, Ernest Tomlinson.
Clogg, Herbert Sherwell.
Cogswell, Philip Dare.
Coltart, Guy Hemming.
Coltart, Henry Neville.
Colyer, Stanley William Randolph.
Cooper, Frank.
Crispin, Edward Smyth.
Dalgado, Patrick.
Darby, William Sydney.
Davies, David.
Eason, Herbert Lightfoot.
Eddison, Francis Ryalls.
Eichholz, Oreste.
Ereaut, Harold John.
Evans, John Rees.
Foss, Edwin Vincent.
Fox, Herewald Evelyn Croker.
Frankling, Herbert George.
Fuller, Laurence Otway.
Galloway, William Hearfield.
Gardiner, Alexander Stoker.
Glasier, Howard.
Glynn, Ernest Edward.
Harris, John.
Hart-Smith, Humphrey Morshead.
Heath, Francis Harold Rodier.
Henderson, John Hunter.
Hoban, Thomas.
Hollander, Bernard.
Hutchinson, Frederick Ernest.
Irvine, Guy Harle.
Jeffreys, Herbert Castelman.
Johnston, Joseph.
Jones, William James.
Jordan, Alfred Charles.
Keeling, George Sydney.
Lawson, Frank Howard.
Leaning, Robert Craske.
Letchworth, Thomas Wilfred.
MacCallan, Arthur Ferguson.
McGavin, Lawrie Hugh.
McKay, Robert.
McMullen, William Halliburton.
Marrack, George Comyns.
Martin, Francis John Hensley.
Martin-Leake, Arthur.
Maynard, George Darell.
Mayo, Thomas Alfred.
Milner, Norton.
Morris, Frank Mayo.
Morris, John Ignatius Vernon.
Murray, Richard Galway.
Nourse, Arthur William.
O'Neill, Thomas.
Osborde, Harry.
Owsley, George Chetwode.
Page, Algenon Fountain.
Parsons, Arthur Ruscombe Crane.
Payne, Robert Whitworth.
Peake, Arthur Edward.
Pennington, S. B. A. Cullen Carter.
Pierce, George Oliver.
Pollard, Sidney Pochin.
Powell, Cecil.
Powell, John Edward.
Pugh, Charles Grant.
Renshaw, Graham.
Rice, David.
Richardson, Walter Silverwood.
Rowland, Lewis Thomas Archibald.
Rowland, Penry William.
Ryder, Claude Clifford.
Sandison, James.
Saward, Arthur Henry Michael.
Scaping, Harold Massey.
Scholefield, Ernest Hall.
Sills, Clarence Ham.
Simpson, Adam Pearson Hope.
Simson, Colin Coape.
Simson, Harold.
Smith, Sidney Robert.
Smyth, Alexander.
Somerville, John.
Sprawson, Cuthbert Allan.
Spurgin, Percy Bertram.
Sumner, Fred William.
Symes, Ernest.
Tarbet, Peter Rowley.
Telling, Walter Henry Maxwell.
Thomas, Charles James.
Thorp, Harold.
Trotter, Edward.
Tucker, William Hancock.
Turner, James William.
Turton, Edward.
Underhill, Sydney V. Hercules.
Unwin, William Howard.
Urwin, John Johnson.
Vernon, Alexander Apfell.
Verley, Reginald Charles.
Walker, Arthur Nimmo.
Wilcox, Richard Loy.
Woodforde, Robert Edmond Heighes.

The following gentlemen passed the First Professional Examination for the diploma of Fellow:—

Monday, Nov. 14th:

Robert Ainslie Ross, Maurice Vincent Dee, M.R.C.S. Eng., L.R.C.P. Lond., M.B., C.M. Edin., Edinburgh University and King's College, London; Herbert Stanley French, B.A. Oxon., Oxford University; Henry T. Hadley Williams, M.R.C.S. Eng., L.R.C.P. Lond., M.D. Western University, Ontario, and Edinburgh University; Henry Rollinson Whitaker, St. Bartholomew's Hospital; William Wright, M.B., Ch.B. Vict., Owens College and Royal Infirmary, Manchester Stanley Copley, M.R.C.S.

Digitized by Google

Eng., L.R.C.P. Lond., Guy's Hospital; Thomas Copeland Savage, University College, London; and Alec. Leslie Matthews, London Hospital.

Seven gentlemen were referred to their professional studies for six months.

Tuesday, Nov. 15th:

William Henry Clayton Green, B.A. Cantab., Cambridge University; Hugh Davies-Colley, B.A. Cantab., Cambridge University and Guy's Hospital; Evan Laming Evans, M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., Cambridge University, St. Bartholomew's Hospital, and King's College, London; Arthur Maurice Colloutt, M.B. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital; Bertrand Seymour Jones, St. Thomas's Hospital; Henry Bennett Bailey, M.R.C.S. Eng., L.S.A. Lond., M.D. Brux., Guy's Hospital; Alwyne Compton Norman Maclaren, B.A. Cantab., St. Bartholomew's Hospital; Bernard Elwell Potter, M.R.C.S. Eng., L.R.C.P. Lond., Charing-cross Hospital; Arthur Hubert Brodribb, M.R.C.S. Eng., L.R.C.P. Lond., St. Mary's Hospital.

Six gentlemen were referred to their professional studies for six months.

Wednesday, Nov. 16th:

Shapurji Hormasji Modi, M.R.C.S. Eng., L.R.C.P. Lond., L.M. & S. Bombay, Grant Medical College, Bombay, St. Bartholomew's Hospital, and King's College, London; George I. Thompson Stewart, M.B., C.M. Aberd., Aberdeen University and St. Thomas's Hospital; John Atkins and Thomas Frederick Robinson, Guy's Hospital.

Twelve gentlemen were referred to their professional studies for six months.

Thursday, Nov. 17th:

John William Thomas Walker, M.R.C.S. Eng., L.R.C.P. Lond., M.B., C.M. Edin., Edinburgh University and Middlesex Hospital; Frank Everitt Murray, Cambridge University and St. Bartholomew's Hospital; Arthur Edmunds, King's College, London; Francis Dawson Blandy, Middlesex Hospital; Charles Ernest West, Oxford University and St. Bartholomew's Hospital; Lawrence Jones and William Francis H. Coke, St. George's Hospital; Michael Foster Reaney and Frank Challans, London Hospital.

Seven gentlemen were referred to their professional studies for six months.

Friday, Nov. 18th:

Edmund Henderson Hunt, B.A. Oxon., Oxford University and St. Bartholomew's Hospital; Thomas Waddelow Smith, M.R.C.S. Eng.; L.R.C.P. Lond., King's College, London; and Harold Walker, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital.

Five gentlemen were referred to their professional studies for six months.

UNIVERSITY OF LONDON.—At the B.Sc. Examination the following candidates were successful:—

First Division.—Charles Edmund Ashby (i., iii., iv.*), Owens College, Pharmaceutical Society and University Tutorial College; Frank B. Barrett (iii., iv., viii.), Mason University College; Albert William Bartlett (v., vi., viii.), Royal College of Science and private study; Alfred George Cracknell (i., ii., iii.), University Tutorial College; Henry Thomas Davidge (i., ii., iii.), Royal College of Science and private study; William Henry Eccles (i., ii., iii.), Royal College of Science; James Lewis Forbes (iii., iv., v.), University Tutorial College; William George Freeman (v., vii., viii.), Royal College of Science; William Henry Harwood-Yarred (iv., vi., vii.), St. Thomas's Hospital; R. W. H. T. Hudson (i., ii., iii.), St. John's College, Cambridge; W. Allan Picknett (ii., iii., viii.), Royal College of Science and Private study; Richard Thomas Robinson (i., ii., iii.), private study; Frank Shedden (iii., iv., viii.), Mason University College; and H. H. Swinnerton (v., vi., viii.), private study and Royal College of Science.

Second Division.—Sophia G. L. Adams (i., ii., v.), Royal Holloway College; Richard Appleton, B.A. (iv., viii., ix.), University Tutorial College and People's Palace; John Sydney Bailey (i., iii., vi.), University College, Sheffield; Anne E. A. Baker (iv., v., vii.), Bedford College, London; George William Baker (iv., v., viii.), private study; Frank Barlow (v., vi., ix.), Royal College of Science and private study; George Robert Barnard (i., ii., iii.), King's College and private study; S. E. Baynes-Smith (v., vi., vii.), University College, Sheffield; John Cardew Bedwell (iv., v., viii.), private study and University Tutorial College; Mary Bell (i., iii., iv.), Ladies' College, Cheltenham; Emily Mary Berridge (i., iii., v.), Royal Holloway College; Agnes G. D. Bigby (i., iii., v.), University College and University Tutorial College; Arthur William Bird (i., ii., iii.), private study and University College, Nottingham; Stuart Blofeld, B.A. (i., ii., iv.), University Tutorial College, Birkbeck Institute, and private study; Ernest Edward Brooks (i., iii., iv.), private study; Alfred Edwin Case (i., iii., iv.), Mason University College; Thomas John Cheater (iv., v., ix.), Finsbury Technical College and private study; Herbert Richard Chilton (i., iii., iv.), private study; Ernest Clark (i., iii., iv.), University College, Sheffield; John Alexander Clark (i., ii., ix.), and Ethel M. Conder (i., v., viii.), University College, Aberystwith; Arthur Samboll Cox (i., ii., iii.); Hartley College and Royal College of Science; Ernest Crosland (ii., iii., iv.), Royal College of Science and private study; Alexander N. * The numerals in parenthesis indicate branches of the examination.

SOCIETY OF APOTHECARIES OF LONDON.—In November the following candidates have passed in the subjects indicated:—

Surgery.—W. H. I. Bathurst (Section I.), London Hospital; E. R. R. Cheesman, Charing Cross Hospital; E. L. D. Dewdney, King's College Hospital; E. E. Evans, Royal Free Hospital; J. B. Hall (Section I.), Leeds; J. Welsh, Dublin; and J. M. Wood, Middlesex Hospital.

Medicine.—H. J. De Saram, Middlesex Hospital; J. E. H. Scott, Leeds; T. J. Vick, Guy's Hospital; and A. F. Weston (Section II.), St. George's Hospital.

Forensic Medicine.—J. E. H. Scott, Leeds; and T. J. Vick, Guy's Hospital.

Midwifery.—G. H. Bedford, Guy's Hospital; R. F. Ellery, St. Bartholomew's Hospital; J. B. Hall, Leeds; P. O'Sullivan, Dublin; J. E. H. Scott, Leeds; and H. J. Watts, Manchester.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: Messrs. E. R. R. Cheesman, H. J. Watts, J. Welsh, and J. M. Wood.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berne:* Dr Wilhelm Zimmermann, prosector of the Anatomical Institute, has been appointed Extraordinary Professor of Anatomy. *Geneva:* Dr. de Marignac has been appointed to the chair of Gynæcology. *St. Petersburg (Military Medical Academy):* Professor A. Lebedeff has been appointed to the chair of Midwifery and Gynæcology in succession to the late Dr. K. Slavianski.

PRESENTATIONS TO MEDICAL MEN.—At the last of the course of ambulance lectures provided by the Surrey County Council Technical Education Committee given by Mr. Laurence Potts, M.R.C.S. Eng., of Leatherhead, on Nov. 10th, he was the recipient of an engraved silver cigarette case as a token of appreciation of his services. —On Nov. 12th, at the Wicker Congregational Lecture-hall, Burngreave-road, Sheffield, the Lord Mayor of the city presented certificates to the successful members of the Midland Railway Goods Department, Sheffield, Ambulance Class and afterwards presented Mr. John H. Brown, M.D. Edin., lecturer to the class, with an electro-plated flower-stand bearing this inscription, "Presented by the Midland Railway Ambulance Class to their lecturer, J. H.

Digitized by Google

Brown, M.D., November, 1898."—In the Bath Hotel, Glasgow, on Nov. 18th, in the presence of a large meeting of friends, Mr. D. Campbell Black, M.D. Glasg., was presented with his portrait painted in oils. The Rev. Dr. Maclean, St. Columba Church, presided, and in presenting the portrait expressed the hope, on behalf of Dr. Black's many friends, that he might long be spared to adorn his profession and to continue his unselfish work in the community.

COLSTON DAY IN BRISTOL.—Colston Day was celebrated at Bristol in the usual manner on Nov. 14th, and the customary banquets took place in the evening, at which the collections for the various charities amounted to £4355, as against £3551 in 1897.

THE TALLERMAN TREATMENT AT BADEN.—The Tallerman apparatus has been placed in the Landesbath and has been visited there by the Grand Duke and his guests. It is not often that the Germans borrow an idea in practical therapeutics from the English; we therefore note the adoption of the Tallerman system at Baden with interest.

A CLERGYMAN ON SANITATION.—The Rev. D. Watcyn Morgan, vicar of Morriston, in the course of his sermon on Nov. 13th, is reported to have said that "diphtheria is now prevalent in our midst and many parents, made disconsolate by the deaths of their children, in their moments of despair have doubtless felt inclined to blame Providence. Do not blame Providence: blame the Swansea corporation, and blame yourselves for allowing the laws of sanitation to be ignored."

QUEEN'S FACULTY OF MEDICINE, MASON UNIVERSITY COLLEGE, BIRMINGHAM.—The annual dinner of the medical students (present and past) of this faculty was held at the Grand Hotel, Birmingham, on Nov. 10th, Mr. Frank Marsh presiding, Mr. Lucas and Mr. Leedham-Green being the Vice-presidents. Many past students and members of the hospital and college staffs were present, including Sir James Sawyer, Mr. Jordan Lloyd, Mr. Haslam, Mr. Eales, Dr. Foxwell, Mr. Gamgee, Mr. Morrison, Dr. Kauffman, Dr. Russell, Mr. Heaton, Dr. Thomas Wilson, and Captain Nott, I.M.S. Letters of apology were received from Sir Walter Foster, Dr. Windle (Dean), Dr. Heath (Principal of the College), Dr. Robert Saundby, Dr. Simon, Mr. Gilbert Barling, Dr. Chavasse, Dr. Carter, Mr. Bennett May, Mr. Priestley Smith, Dr. Douglas Stanley, and others. After proposing the toast of "The Queen," which was enthusiastically received, the President gave "The Students, Past and Present." He referred to the many men of distinction who acknowledged the Birmingham Medical School as their *alma mater*. It was with very great pleasure that he was able to welcome such a large number of present students to this dinner. Meetings of this kind helped to promote that *esprit de corps* and feeling of good-fellowship which was so essential in the medical profession. He referred with emphasis to the important part which athletics played in a man's career. He advised students to take their part in sports, adding that "a good athlete is a good student." He alluded to the active duties of a medical man on the battle-field, mentioning the recent Soudan campaign as evidence of the laborious and unceasing toil of medical men at the front. Sir James Sawyer responded to the toast on behalf of the past students, urging on qualified men the necessity of taking up a hobby of some description so as to give them relief and change from their professional duties. Mr. Satchwell Smith replied for the present students. Mr. Eales then proposed the toast of "The Medical School," congratulating the students on the excellent opportunities afforded them, and expressing the hope that some day all the hospitals in Birmingham would be amalgamated for the purpose of clinical study. Mr. Haslam (honorary secretary, Clinical Board) responded, remarking that in his opinion the Birmingham Medical School was second to none in the kingdom. Mr. C. Leedham-Green proposed the toast of "The Visitors," to which Mr. H. A. Pearson (coroner for South Staffordshire) responded in a humorous speech. Mr. Jordan Lloyd proposed the toast of "The Officers of the Dinner," mentioning the cordial relations which he was pleased to say existed between the teachers and those taught. Mr. Lucas and Mr. F. W. Bywater suitably responded. A short musical programme brought the proceedings to a close.

THE AUTUMN MEETING OF THE IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.—The autumn general meeting of the above Association, which now numbers 750 members, was held on Wednesday, Nov. 23rd, at the Café Monico, the President, Dr Mapother, being in the chair. There was a large attendance of members. A vote of thanks was given to Dr. Abraham for his admirable conduct of the business of the association as chairman of the Council during the three years just concluded and a similar compliment was paid to Mr. O'Callaghan for his services in promoting the success of the gatherings of the society during the last two years. A new rule was passed enabling the erasure of the name of any member from the roll whose name had been removed by the General Medical Council from the Medical Register. An addition was made to the list of officers of the association, on account of the increasing number of provincial members, in the person of a vice-president of the Council. The chairman of the Council announced that it was the intention of the Council to immediately consider the question of how far the association could further the movement on the part of the Universities of Ireland for obtaining powers to deprive of their degrees those who had committed any offence leading to a conviction in courts of law or deprivation of the right to have their names on the Medical Register. The members and their friends, to the number of 161 subsequently proceeded to dinner. Sir William Mac Cormac Bart., K.C.V.O., President of the Royal College of Surgeons of England, whose health was proposed in a highly laudatory speech by Dr. Mapother, gave some interesting details of his past professional life and said that much of his success was due to the support and encouragement which he had received from, first, his wife and, secondly, his medical brethren in London. A large number of ladies were present, including Lady Mac Cormac. The evening was enlivened by Irish songs rendered by Miss Gladys Grove, R.A.M., and Mrs. S. F. Freyer, Miss Maud Jaques being at the piano.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

AN UNSIGNED MANUSCRIPT.

"*On the Bacteriological Diagnosis of Diphtheria and the Desirability of providing Local Facilities for its use by the Profession Generally.*"—A manuscript bearing the above title is in our possession. It bears neither name of an author nor an address. Will the author kindly communicate with us?

A POINT OF ETIQUETTE.

A CORRESPONDENT writes as follows:—"A and B are medical men practising, in the same town. One of A's patients calls on him with an urgent request that he will see his wife. A is not at home and on his return finds a letter from the patient saying that as the case did not permit of delay he had called on A's partner, but not finding him at home had obtained the services of B, so that it would not be necessary for A to call at present. A writes to B thanking him for his courtesy in seeing the case. Previously, however, to receiving this letter B notifies A that the patient has called on him (B) asking him to attend his wife in future. A thereupon forwards to B the patient's explanatory letter and intimates that he considers B should decline further attendance. B replies that he has adopted this course. The patient then calls on A, apologising for

Digitized by Google

having called in B, regretting A was not at home, and pleading the emergency of the case. In reply to A's query as to why B had continued attending when A was available he states it was at his request, as his wife was about to proceed to London in a couple of days and it did not appear necessary to 'change doctors.' On the following morning B meets A and informs him that on the previous evening the patient had called on him requesting him to continue attendance and suggests that it shall be left to the patient's option as to whom he will send for in future. A demurs to this proposal, urging that such will constitute the patient an arbiter in a matter of professional etiquette and again calls on B to retire from the case, maintaining that had either he or his partner been at home B would not have been sent for. B absolutely refuses to surrender the case and states that he intends to attend in future whenever summoned. A then writes to the patient pointing out his very inconsistent conduct and demanding an explanation, and receives a reply to the effect that he wishes B to attend in future. Under these circumstances, (1) was B justified in continuing attendance after the real facts of the case were notified to him by A? and (2) is he justified in continuing to act as medical attendant to the family?"

*** The routine dictated by professional etiquette and no less by good feeling is well known. When a practitioner is called to an urgent case usually attended by another medical man he must, when the emergency is provided for, resign the case. But seeing that the patient was only to be two more days under a medical man's care in this neighbourhood we can understand her husband's feeling in desiring that no change should be made in her medical adviser. It seems probable that matters could have been arranged in this way amicably if A, B, and the husband had conferred together. Is it too late for such a meeting? B ought not to attend the patient, but, judging from the statement of one side only, it seems quite clear that if B does not attend A will not be asked to attend. Such a situation would only punish the patient and her husband, who are not supposed to know all about medical etiquette.—ED. L.

MONSTERS.

To the Editors of THE LANCET.

SIRS,—Can you kindly inform me where I could find the best description of anencephalic monsters and of congenital deficiencies of the skull? I am, Sirs, yours faithfully,

Nov. 20th, 1898. J. B. ADDISON.

*** Our correspondent should consult Hirst and Piersol: "Human Monstrosities," part ii., Pentland, 1892; Hughes: THE LANCET, Dec. 17th, 1887, p. 1212; and Lancereaux: "Anatomie Pathologique," vol. i., Delahaye, 1875.—ED. L.

WANTED A HOME.

To the Editors of THE LANCET.

SIRS,—I am much exercised to know what to do with a young fellow of feeble intellect who is without relatives to take charge of him, but who is in possession of a small capital which provides about £50 per annum. He has been for some years past in a provincial town, but as he gets older he becomes more troublesome and has lately given much annoyance. He is not vicious at all, but his vagaries take an obtrusively religious form mingled with much vanity. Personally I think he would be better under certificates, but he cannot be treated as a pauper and it is difficult to find suitable quarters for him where the available income is so small. If any of your readers could help me I shall be most grateful. I am, Sirs, yours faithfully,

Nov. 18th, 1898. G. H.

"SCARLATINIFORM ERUPTIONS IN INFLUENZA."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 12th "Eruption" asks for information regarding cutaneous rashes accompanying attacks of influenza. A reference to the "Medical Digest," Section 655:1, will show that they have been described since 1890 by both English and foreign observers.

I am, Sirs, yours faithfully,

RICHARD NEALE, M.D. Lond.

Finchley-road, Hampstead, N.W., Nov. 17th, 1898.

ENDERMIC MEDICATION.

To the Editors of THE LANCET.

SIRS,—Will you kindly inform me through THE LANCET whether there is an institution in London where the endermic treatment of syphilis by mercury is carried out? I have a patient whom I am anxious to send over. I am, Sirs, yours faithfully,

Nov. 22nd, 1898. VIENNA.

*** We do not know of any institution specially devoted to this method.—ED. L.

THE TENDER MERCIES OF THE PARAGRAPHIST.

THERE is an amusing little paper called *M. A. P.*, edited, we believe, by a Member of Parliament who is also a very able journalist. Therefore we are sorry to see twaddle of the kind we quote admitted into its columns, and we are quite sure that Miss Arabella Kenealy and Dr. Jane Walker will not be particularly pleased at being bracketed with irregular practitioners like "Dr. Muriel Maitland King" and "Dr. Longshore Potts." We learn that "Dr. Muriel Maitland King, the nerve specialist, has an extensive and fashionable *clientèle*, and at her parties in Park-street, W., one is sure to meet many social stars." This lady also finds time to give "most interesting lectures on various phases of nervous exhaustion, insomnia, *embonpoint*, and other subjects attractive to women." The paragraphist kindly informs us that Dr. Longshore Potts is over sixty years of age, and he waxes eloquent over the complexion and manners of Miss Kenealy and Dr. Walker. We are quite certain that the two latter ladies have nothing to do with the insertion of these particulars, but we hoped for better things from the editor of *M. A. P.*

TREATMENT OF VARICOSE ULCER.

To the Editors of THE LANCET.

SIRS,—I shall be very glad if any of your readers could suggest a method of treatment for the following condition. The patient, an elderly woman, has suffered for several years from a large varicose ulcer on the lower and inner third of the right leg. The ulcer is 3 in. in length and 1½ in. in breadth, the surrounding tissues are hard and inflamed, and the pain is very severe at times. Complete rest in bed for some weeks has been tried, but with little success, likewise indiarubber bandaging, strapping the limb, &c., have received their due share of attention, while various lotions and ointments have been applied to the surface of the wound. The patient has become reconciled to the ulcer if she could obtain relief from the almost constant pain, and therefore I should be glad to hear of any lotion or ointment which would have the desired effect of relieving the pain.

I am, Sirs, yours faithfully,

Nov. 22nd, 1898. "ULCER."

Mr. James Griggs.—Our correspondent will find the names and addresses of various institutions of the kind in "Burdett's Hospitals and Charities" or "The Annual Charities Register and Digest" (Messrs. Longmans, Green and Co.).

Filter.—We see no novelty in the arrangement or in the material employed, and we very much doubt whether by this means a bad water would be made safe.

Mr. A. Bennett.—We never prescribe. If our correspondent's means do not permit of his calling in a medical man he had better seek advice at a hospital.

Kentigern.—The article referred to appeared in the *Asclepiad* in 1887, p. 301.

Worried.—We do not prescribe. The patient should consult a medical man.

S. E. H. has omitted to enclose his name and address.

Cape Colony.—We know of no such journal.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

FAT IN HEALTH AND DISEASE.

THE ONLY FAT FOOD
IS
SAVORY & MOORE'S
PANCREATIC EMULSION.

FAT forms about 18 per cent. of the adult human body. It is stored up as a reserve in adipose tissue, and the loss falls chiefly upon this in starvation or in the wasting of disease, so that nearly the whole of the fat may disappear. Adipose tissue is very fluctuating in quantity. A large amount may disappear in a very short space of time, and within an almost equally short period the quantity present in a body may be several times multiplied. Stored-up fat comes from the fat of food, which in an ordinary diet varies from one to two and a half ounces. It is also formed from carbo-hydrates, such as starch and sugar, but both these substances, especially sugar, are frequently clinically counter-indicated. Fat is naturally indicated in all cases of wasting and loss of weight, and, conversely, a tendency to corpulency may be counteracted by restricting the fats and carbo-hydrates and increasing the proportion of proteid which augments the general metabolism of the body.

Digestion consists in the conversion of non-diffusible proteids and starch into more diffusible peptone and sugar and in the emulsifying of fat by its division into minute particles. In certain diseases the action of the pancreas on fat is weakened, if not entirely suspended, with the result that much of the fatty part of the food passes through the intestine undigested.

The action of the healthy pancreas on fat is chiefly an emulsifying one, though under some conditions there is also an appreciable splitting up of the fat into its component fatty acids and glycerine. The fluid containing the elaborated product of digestion in its final stages—viz., chyle—owes its whiteness and opacity to fat, of which it often contains, after a meal, as much as 5 per cent., the fat existing in the form of exceedingly minute spherules or granules, far smaller than any globules to be seen in milk. It is the most perfect emulsion known, and is the only one that is not broken up by the action of ether.

The immense importance of maintaining the proper proportion of fat in chyle will be realised when we consider that an amount of chyle equal to half the whole blood of the body may pass through the lacteals from the alimentary canal in the twenty-four hours. The formation of an Emulsion of Fat, *identical with the emulsion as it exists in chyle passing through the lacteals*, has now been arrived at, outside the body, by the action of the pancreas. This Emulsion is known as *Pancreatic Emulsion*, and by its means we can present the fat of food in the condition necessary for immediate assimilation where the natural power of emulsifying fat is lost or impaired.

In disease arising from defective nutrition, and in phthisis and all scrofulous conditions, fat is often found of the greatest benefit. It is also invaluable in the convalescence of acute disease, and as a tonic to the nervous system in neuralgia and nervous debility. It is obviously an advantage in a dietary to give solid animal fat, which, like human fat, contains a considerable proportion of stearin and palmitin, as well as olein, in preference to a fat like cod-liver oil, which consists almost entirely of olein. "PANCREATIC EMULSION" provides the natural fat of food, emulsified so that it can be assimilated and absorbed with the greatest ease. Experience shows that it is free from the drawbacks so often attending the administration of cod-liver oil, and that it can be continued for any necessary length of time without disagreeing or causing nausea or diarrhœa, and that a rapid increase of weight and immediate improvement in health result from its use.

The Emulsion is a perfectly neutral one, formed solely by the action of the pancreas, is absolutely unobjectionable in taste, easily miscible with fluids, and of the consistence of Devonshire cream. It keeps sweet and good for years in any climate and may be obtained of all the principal Chemists throughout the world.

In bottles 2/6, 4/6, and 8/-, with special terms to Hospitals and Infirmaries.

"APENTA"

THE BEST NATURAL APERIENT WATER.

APENTA WATER IN THE TREATMENT OF OBESITY.

"The *Berliner Klinische Wochenschrift* for March 22nd, 1897, speaking of some experiments made under Professor Gerhardt's direction in the Charité Hospital as to the value of APENTA water in the treatment of obesity, says that such experiments could not be carried out until quite recently, on account of the inconstant composition of the bitter waters coming into the market. In this respect, the APENTA water is favourably circumstanced, and it was chosen for these observations because of its constancy of composition. The conclusions arrived at as to the value of APENTA in the treatment of obesity, and as to its influence on tissue-change without causing any nutrient losses, were that it succeeded in producing a reduction of fat in the body without detriment to the existing albumen, and that the general health of the patient suffered in no wise, and the cure ran its course in a satisfactory manner."

A Clinical Lecture

ON

A CASE OF GALL-STONES IN THE COMMON DUCT CAUSING SIMPLE INFECTIVE CHOLANGITIS.

Delivered at Guy's Hospital on Nov. 19th, 1898,

BY W. HALE WHITE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO GUY'S HOSPITAL.

GENTLEMEN,—The case I want to bring before you is a very long one, so I have abbreviated the excellent report by Mr. W. P. Ker. A married woman, aged thirty years, was admitted into Mary Ward on July 20th, 1898, for pain in the right side of the abdomen, vomiting, and a temperature of 103·2° F. Her history did not begin to be important till eight months before, when she had a severe attack of pain in the right side of the abdomen and back. Three weeks before admission she had a similar attack, this time accompanied by jaundice and very light-coloured motions. One week later she had a third attack and since then she has had repeated attacks of pain and vomiting, accompanied by high temperature. During this fortnight her motions have been clay-coloured, she has sweated profusely, has had some shivering, and has felt very ill. On admission she was found to be slightly jaundiced; her temperature was 103·2°, her pulse was 104, and her respirations were 40. She was very thirsty. Her bowels were regular and the stools were light-coloured. The liver reached nearly to the umbilicus; it was uniformly enlarged, firm, tender, and smooth. There was a very tender point to the right of, and slightly below, the umbilicus. At this spot we thought there was an ill-defined swelling which might have been a gall-bladder, but we were not certain about it. The respiratory, circulatory, nervous, and generative systems did not present any symptoms to call for comment. The urine contained some bile, otherwise it was healthy. She was obviously in great pain. Soon after admission she had a rigor. She had had three shortly before admission. The diagnosis made was that the patient was suffering from gall-stones which being in the common duct caused the jaundice and enlarged liver, and that they, damaging the mucous membrane of the duct, had set up general infection through the branches of the portal vein which return blood from the walls of the duct. Hot fomentations were applied over the liver. The patient was given a little brandy, some lemon juice and barley water, and milk and bread-and-butter. On July 22nd there had been no further rigors, the temperature had ranged about 100°, the jaundice was less, and the liver was smaller and less tender. As a result of an enema she passed three small facetted gall-stones. On the 23rd her condition was about the same as in the last note except that her temperature was about 103·4° on this date. On the 25th she was much better. The liver was smaller, the jaundice was not visible, and the pain and tenderness were less. The temperature was normal. She continued to steadily improve and had a nearly normal temperature till August 6th, when she had another rigor and the temperature rose to 102·8°; we thought that day that the gall-bladder could be felt to be enlarged. In spite of the rigor she had very little pain and tenderness over the liver. On the 9th she had another rigor. The temperature this time was 101·6°. From this date until August 31st she had very irregular temperature; usually it was normal or below normal in the morning and rose to between 101° and 104° in the evening. Often this rise was accompanied with rigors, but they were never severe. More often, however, she simply complained of feeling cold all over; occasionally she was sick. She was not jaundiced during these three weeks nor was there much tenderness over the liver, and this organ was not so large as before. In spite of this long-continued severe pyrexia she maintained her ground fairly well although she sweated and looked ill. On the 30th she passed three fair-sized gall-stones. On Sept. 6th she was much better. On that day she passed some large gall-stones, the largest being of the size of a cherry-stone. On the 11th she had an attack of pain over the region of the gall-bladder. This part of the abdomen was so tender that nothing could be made out on palpation. On the 17th she had another attack of severe pain in the same region. Her temperature at the same time rose to 102·6°. On that morning a large three-cornered gall-stone was found in her motions. The liver was rather enlarged again, reaching down to the umbilicus. On the 26th she had another rigor and an attack of pain. On Oct. 1st she had another rigor, an attack of pain, and a rise of temperature to 102°. On the 3rd the patient passed two gall-stones, one of which was the largest she had ever passed. On the 8th the patient got up. From this time until the 16th she did uniformly well. She went out on the latter day. Her liver then reached to 1½ in. above the umbilicus, she was in no pain, and she had no tenderness over the gall-bladder. She looked quite well, and in spite of her attacks of pain and her rigors she had been gaining ground steadily since Sept. 1st.

No special treatment was adopted. Hot fomentations, morphia injections, and slight inhalations of chloroform were used to relieve the pain. She was given plenty of light nourishing food and she was always enticed by variations of diet to eat as much as possible. Usually she was taking some gastric carminative stimulant medicine and her bowels were always kept thoroughly open. During part of her illness some anti-streptococcic serum was used, but it was left off as it had no beneficial effect.

I think the easiest way for us to handle this case will be to first of all consider what could be the cause of the jaundice. You will find enormously long lists given of the causes for jaundice, but in actual practice it is in adults nearly always due either to (*a*) the disease called catarrh of the ducts or simple jaundice; (*b*) cirrhosis; (*c*) cancer of the glands in the portal fissure or of the head of the pancreas; (*d*) some specific fever, usually yellow fever, ague, more rarely acute yellow atrophy, or epidemic jaundice; (*e*) phosphorus poisoning; (*f*) congestion of the liver, in this country, at least, due to backward pressure from the heart or lungs; and (*g*) gall-stones in the common duct. From time to time we see patients suffering from jaundice due to other causes, as in the man we had in the hospital some time ago in whom it was due to a moveable kidney, but they are so rare as to be mere curiosities.

Now our patient was far too ill to be suffering from (*a*) catarrhal jaundice; in this disease the patient is not very ill, he has indigestion and jaundice with very little pain, and is in a few days quite himself again. Probably the disease is due to catarrh of the duodenum spreading into and closing the duodenal orifice. Although both cirrhosis and cancer of the liver, especially cancer, may be accompanied by a raised temperature it is never so high in cirrhosis as it was in our patient, and it would be quite exceptional to find so much pyrexia in cancer, although some striking instances are recorded by Osler. But our patient was very young for cancer, there were none of the other signs of it, and the pain from which she suffered was not at all like it. Specific fevers of this country are very rarely accompanied by jaundice; there was no evidence that she had been anywhere where she could contract ague, and her whole illness was unlike it. She had not got phosphorus poisoning and she had no cause for congestion of the liver, so you see that by a process of exclusion we were able quickly to arrive at the diagnosis that she was suffering from gall-stones, a view which was confirmed by the history of paroxysmal attacks of pain in the region of the liver. Indeed, her account of them showed that they were so severe and constant in position that in a woman they were of themselves almost enough to establish a diagnosis of gall-stones.

You will notice that I have drawn no distinction between obstructive jaundice and non-obstructive. My reason is that the exact mode of production of jaundice is often so obscure that it is, I think, better at the bedside not to draw such a distinction, for it may lead you into error. In many instances there is undoubtedly an obstruction, but in some it is very doubtful whether there is; probably in some forms of jaundice, as, for example, that associated with malaria, the yellow pigment is produced in the blood; but we must to-day keep to the clinical side of the case.

The other point to which I have not alluded is the statement made by the patient that the stools were light. Patients are such bad observers, shades of colour are so difficult to describe, and the stools vary naturally so much in colour that you should give very little weight to a statement about the colour of the stools. Always examine them yourselves and even then remember that they may be very pale, especially if much milk be taken, quite apart from any

Digitized by Google

obstruction to the flow of bile. Before you can decide from them that probably the bile-duct is obstructed they ought to be of a light clay colour, hard, and usually foul-smelling.

Gall-stones are very common. The figures from the Strasburg Hospital show that 20·6 per cent. of all the female bodies examined contained them. They are especially common in married women and are very frequent in the decade from thirty to forty, so that you see they are very common in people of the age, sex, and condition of our patient. Fortunately, however, the sufferers from them do not often suffer as our patient suffered. Usually they have attacks of pain more or less severe, and then as they grow older the attacks cease. Any of you who have attended necropsies regularly will bear me out in the statement that it is very rare to see death attributable to gall-stones, but it is also rare for elderly persons to complain of the symptoms produced by gall-stones, so we may conclude that, as a rule, either the stones are passed or they remain quiescent in the gall-bladder, and in favour of the latter statement is the well-known fact that they are frequently found in the bodies of those in whom they were quite unsuspected during life.

In passing I should like you to notice that our patient's account of her earlier attacks of pain was very typical, for she made it quite clear to us that her pain was agonising, sudden in onset, paroxysmal, and situated in the hepatic region. She, like other women, said that it was worse than the pain of labour. With her, as is usually the case, it lasted a few hours.

The next fact I want to bring before you is that the passage of a stone along the common duct not only frequently gives rise to an ordinary attack of biliary colic and transient jaundice, but, as shown in our patient's earlier and late attacks, these two symptoms may be accompanied by a rigor and a rise of temperature. Ordinarily the temperature is only raised a short time, the stone passes, and the patient is well. The cause of the rise of temperature in these cases is unknown. Generally it is thought to be reflex, and I have given you, when lecturing on pyrexia, other instances in which severe stimulation of the peripheral nerves will lead to pyrexia. Perhaps some day these attacks will be shown to be due to a micro-organism infecting from the bile passages and be merely a slight degree of what will be described directly as simple infective cholangitis; if so, they are so much slighter that their clinical importance is quite different.

But the gall-stones in our case caused the patient to look ill, and she had prolonged pyrexia, the temperature in a few hours rising from normal to a considerable height, many rigors, attacks of sweating, vomiting, and an enlarged tender liver, in addition to her pain and jaundice. Gall-stones may produce these symptoms in the following ways: (*a*) The stone may set up inflammation of the duct with subsequent ulceration or perhaps the formation of a local abscess. Pyæmic infection may follow because the venous blood from the wall of the duct is returned into the portal vein, and as a result multiple small pyæmic abscesses in the liver may be formed. This condition of portal pyæmia is always fatal. (*b*) Stones in the common duct may cause pain, jaundice, sometimes severe, but often slight and variable (in which case we must suppose the duct is not completely blocked), an enlarged and tender liver, rigors, sweating, vomiting, and pyrexia lasting for many days without the formation of secondary abscesses in the liver. The probable explanation is that in these cases also there is inflammation of the mucous membrane of the common duct with subsequent infection, but if this is the right explanation it is a different kind or degree of infection from that which leads to multiple small abscesses in the liver, for patients may for many years be subjected to attacks like that of our patient. We may, provisionally at any rate, speak of this group as cases of gall-stones of the common duct accompanied by simple infective cholangitis which will distinguish them from cases with pyæmic abscesses and cases of suppurative cholangitis. Both streptococci and bacilli coli are so very variable in virulence that either may well be the cause of groups (*a*) and (*b*). (*c*) The gall-stone may set up suppurative inflammation of the common duct which quickly spreads back and all the ducts in the liver become full of pus; this condition is called suppurative cholangitis. (*d*) The gall-stone in the common duct might have been producing only jaundice and the other symptoms might have been due to an abscess in connexion with some other stone; for example, there might have been an empyema of the gall-bladder in connexion with a stone in it or in the cystic duct.

When our patient came in, ill as she was, she did not seem ill enough to be suffering from suppurative cholangitis, and although we thought that the gall-bladder was tender and perhaps enlarged we did not think the enlargement definite enough, or the tenderness great enough, for there to be pus in it, and we could find no evidence of an abscess elsewhere, so we concluded that either she was in the early stage of (*a*) portal pyæmia due to gall-stones in the common duct, or that she was suffering from (*b*) simple infective cholangitis due to gall-stones in the common ducts. As I repeatedly pointed out to you at the bedside the difference between the two diagnoses was probably only one of degree; in both cases we believed that infection was taking place from the mucous membrane of the common duct and therefore we often spoke of her loosely as suffering from portal pyæmia, but kept the two above possibilities (*a*) and (*b*) before us.

Some of you asked me what the word "cholangitis" meant. It simply means inflammation of the mucous membrane of any of the biliary passages; therefore the word is allied to such words as "gastritis," "enteritis," &c. The word is coming very much into use. It sounds a little uncouth, like most of the modern terminology connected with the bile passages. Fancy how pleased the old woman who liked the word "Mesopotamia" would be if you told her that she had "cystic cholelithiasis associated with infective cholangitis, that if an operation was necessary you could either do cholecystotomy, or cholecystendysis, or cholecystectomy, or cholecystenterostomy, or cholecystolithotripsy, or choledocholithotomy, or choledochostomy, or choledochoenterostomy, or choledocholithotrity, or choledochectomy, or choledochotomy, or choledochoduodenostomy, or cysticolithotomy."

You will remember that on July 22nd the patient passed three gall-stones and that from July 25th to August 6th she was pretty well with a normal temperature. This went a long way to confirm our diagnosis that the gall-stones had caused simple infective cholangitis. From August 9th to August 30th she had such high, irregular temperature that we often feared that after all the gall-stones had set up portal pyæmia with small abscesses in the liver; the only thing against this view was that she did not lose ground so much as would have been expected if it were correct. She improved so much during September that it was quite clear she never had had pyæmic abscesses in her liver and that the diagnosis of simple infective cholangitis due to a gall-stone in the common duct was correct, and the illness during August shows you how severe this infection may be. Whether you should regard the rigors and transitory rises of temperature associated with the passage of gall-stones which occurred during September as mild instances of the same infective process is open to question, but clinically there is no doubt that they are examples of the fact that I have already pointed out to you that the passage of gall-stones will often cause a rigor and transient rise of temperature.

The disease from which our patient suffered—namely, gall-stones in the common duct accompanied by simple infective cholangitis—is fortunately not common. There is a very good collection of eight cases by Dr. Osler in the Johns Hopkins Hospital Reports for January, 1890. I have already given you the symptoms and we will now consider them in detail. The jaundice is usually deep, and, like all long-lasting jaundice, gradually gets darker as time goes on; sometimes, however, as in our patient, it is only slight. Whatever its maximum depth it varies much in intensity from time and may, as in our case, go altogether. Generally when a rigor or chill comes on it deepens considerably, but this was not so with our case. These variations in intensity are difficult to explain, for the stone is always present and in most of the cases some bile must get past it. Possibly the variations are due to variations in the swelling of the mucous membrane near the stone. The jaundice may last for years and it may be accompanied by any or all of the phenomena due to the circulation of bile in the blood. The pyrexia occurs in paroxysms usually associated with rigors. The temperature rises suddenly, sometimes as high as 105°. The patient feels cold, often shivers very severely, her skin is dry, but in the course of a few hours it becomes moist, she sweats profusely, and the temperature falls as quickly as it rose. The paroxysms generally occur at irregular intervals and Dr. Osler says he has seen them recur daily for a week or ten days; but ours was a more severe case, for in the worst group of attacks they occurred daily,

Digitized by Google

sometimes two a day, for three weeks continuously. In very mild paroxysms a slight rise of temperature, a feeling of chilliness or sweating may either of them occur alone. Even when the attacks are severe the intervals between single paroxysms or groups of paroxysms may be several days or weeks so that the whole illness may be spread over months or years. Pain is nearly always present. Sometimes it is severe and agonising genuine hepatic colic. In other cases it is very slight, and, as in our patient, it may be very severe during some attacks and not in others. Vomiting often accompanies an attack. Our case illustrates this. There may be nausea and a furred tongue. The liver is generally uniformly enlarged, smooth, and tender. Our case exemplifies this and appears to show that the gall-bladder may be enlarged and tender. It is very noteworthy that the patients do not lose flesh much and quickly recover from their attack. This was very noticeable in our case.

You must bear in mind that the common duct may be completely obstructed by a gall-stone or stenosis for many months without producing the train of symptoms here described. On the other hand, it is said that simple stenosis may cause them.

You see here the gall-stones which this woman passed, and it must at once strike you as impossible for them to get through the narrow orifice by which the duct opens into the duodenum, but you will remember that the duct lies in the wall of the duodenum for ¾ in.; what happens is that the stone lying in this position ulcerates into the duodenum. When once this has occurred other stones can easily pass through the opening.

I do not think that in England there ought to be much difficulty about diagnosis from most other diseases, but in countries where severe malaria is common, and especially where it makes the patients yellow, the diagnosis may be very difficult, for the paroxysms and shiverings which characterise the disease which we are discussing very closely resemble ague, and, indeed, the diagnosis has sometimes been only satisfactorily made after finding the malarial parasite in the blood. But it may be very difficult to tell whether the gall-stone is setting up merely a simple infective cholangitis, suppurative cholangitis, or portal pyæmia, for the diagnosis will rest upon the correct estimation of the severity of the symptoms. A very good example of this difficulty occurred in a woman, aged sixty years, whom I saw with Mr. A. G. Wells. She had rigors, an irregular high temperature, jaundice, a tender liver, and was desperately ill. The position was explained to her friends and in the faint hope that it might turn out to be simple infective cholangitis and that it might be possible to remove a stone Mr. Arbuthnot Lane opened the abdomen, but could not reach the common duct because the parts were so matted from old local peritonitis due to gall-stones. At the post-mortem examination I found the liver studded with pyæmic abscesses, a stone in the common duct, the biliary passages inflamed, and the lining membrane in places gangrenous.

The treatment of the patient the subject of this lecture gave rise to much discussion. Many urged that if I thought there was a stone in the common duct setting up simple infective cholangitis I ought to have suggested an operation, but the following reasons prevented my doing this. If the case had been portal pyæmia or suppurative cholangitis, both of which were possible, an operation could do no possible good; if, on the other hand, the case were one of simple infective cholangitis we could safely wait to see what course the malady would take, for this disease is very chronic, and, bad as our patient was, she never, as far as her general strength went, appeared to lose ground. Then, too, it is a very difficult operation, especially when the liver is very large, to remove a stone from the common duct. In the case I have just mentioned matting prevented Mr. Lane from even reaching the common duct. Out of Dr. Osler's 8 cases 2 were operated upon and both died. Waring quotes Jourdan, who says that out of 72 cases operated upon and published up to 1895 22 died, and when you remember the inevitable tendency for more successful than unsuccessful cases to be published I should think that represents a mortality of about 50 per cent. Then, again, gall-stones are usually multiple and even if you remove the offending one and any there may be in the gall-bladder others will probably be formed later and passed down the duct. So that while I would most certainly not say that operation is never desirable it is very important that you should hesitate for some time before embarking upon such a very difficult and dangerous operation. Probably you never ought to do it if the patient is keeping her ground, for there is always the possibility that she may pass the gall-stones into her duodenum. That fortunate result occurred in our case, and when you see the size of the stones she has passed you will agree with me that her common duct is now probably sufficiently large to admit of the passage of subsequent stones, and as she wrote to me only yesterday and appeared from her letter to be in good health and able to be up and about at her household duties you will see the justification of our not having advised operation. Since she left the hospital she has passed one other gall-stone without much difficulty. The course we adopted of relieving pain, keeping her bowels open, and maintaining her strength appears to be justified by Dr. Osler's figures, for of his 8 cases 2 died after operation, 2 died from the effects of long-continued jaundice, 3 recovered without operation, and 1 passed out of observation.

To sum up, while I am far from saying that you should never advise operation you should always watch the case before advising it, and do not advise it if the patient is not losing ground. If you recommend it and it rests with you to select the surgeon do not do the operation yourself unless you are a skilful surgeon, for it may be very difficult. Want of time prevents to-day a proper discussion of the best means of preventing for the future the formation of gall-stones in our patient.

THE RESULT OF THE TREATMENT OF DIPHTHERIA BY ANTITOXIN IN LONDON COMPARED WITH THAT IN PARIS AND BERLIN.

BY LOUIS COBBETT, M.A., M.B. CANTAB., F.R.C.S. ENG.

IT may appear to some unnecessary at the present time to discuss the evidence of the utility of diphtheria antitoxin. Yet I think that no one who is aware how unfavourably the death-rate and the case mortality of diphtheria in London compare with those of the great continental cities will deny that some inquiry is desirable. The first attempts to cure diphtheria in human beings with the serum of immunised animals were made in 1891 and failed because the antitoxic power of the serum was too small. It was not until 1894 that antitoxin strong enough to produce a marked effect was obtained. Early in that year reports of cases treated by the new remedy were published in Berlin. Some months later the serum treatment received its great impulse from Roux's memorable address to the International Congress of Hygiene and Demography at Budapest, and the serum treatment may be said to have generally commenced in the great cities of Europe from that time. The statistical returns from hospitals and other sources which have appeared since show a very remarkable reduction in the fatality of diphtheria.[1] But several more or less weighty objections have been made to concluding that the new treatment has been the cause of the improvement.

In the first place, it has been argued that the bacterial method of diagnosis which was introduced about the same time as the antitoxic treatment has caused a considerable increase in the number of cases reported as diphtheria, the increase consisting chiefly of cases which, without the aid of the new test, would have been regarded as cases of simple sore-throat. But it must not be forgotten that the new test has also eliminated a considerable number of cases of membranous pharyngitis which previously would have been regarded as diphtheria. On this point Professor Welch concludes that the new test has on the whole excluded more mild cases than it has admitted.

In the second place it has been said of hospital statistics that the smaller fatality of diphtheria which they show in recent years may be accounted for on the supposition that the fame of the new remedy has attracted more patients to the hospitals, with the result that the average severity of the

[1] In 1895 Professor Welch of Baltimore collected 82 reports dealing with a total of over 7000 cases treated with antitoxin, of which the average fatality was 17·3 per cent. In 45 of these reports the previous or simultaneous fatality was given and averaged 42·1 per cent. (The Treatment of Diphtheria by Antitoxin, Transactions of the Association of American Physicians, vol. x.)

Digitized by Google

cases admitted has declined. This is certainly not true of the Berlin hospitals, as a glance at Table II. will show. For there the ratio of the cases treated in the hospitals to those occurring in the whole of the city has not increased since the introduction of the serum treatment. On the other hand, the ratio of admissions for diphtheria into the hospitals of the Metropolitan Asylums Board to notifications in the whole of London has considerably increased. Nevertheless, the severity of the cases treated there does not seem to have lessened. For the medical superintendents reported[2] that in their opinion the average severity of the cases treated in 1895 was about equal to that of those treated in 1894, the death-rate in that year having been slightly lower than that of any previous year; and that "during 1896 a larger proportion of children under five and ten years and of cases admitted on the fourth day or later have been under treatment than was the case in 1895, so that, other things being equal, a heavier mortality was to be expected." Again, "the years 1895 and 1896 were somewhat worse off than 1894—viz., in the proportion of cases in which laryngeal symptoms were present before admission to the hospital, the percentage of such cases on the total admissions being—in 1894, 11·4; in 1895, 15·1; and in 1896, 13·5."

In the third place it has been suggested that the introduction of the new treatment has been followed by a succession of years during which the disease has been of a mild type. In answer to this the opinion of the medical superintendents may be again cited as to the type of diphtheria recently prevalent in London. But even if it had been so it would probably not have affected the hospital statistics to any great extent. For when diphtheria is of a mild type a larger proportion of cases remain at home than when it is severe, so that the average severity of the hospital cases remains fairly constant.

In 1894 Roux, Martin, and Chaillou[3] reported 300 cases treated with antitoxin in the Hôpital Trousseau, in Paris, with a fatality of 26 per cent. During the period referred to in the report the fatality of the Hôpital des Enfants-Malades, where the antitoxin was not used and where the fatality in diphtheria had always approximated very closely to that of the Hôpital Trousseau, was 60 per cent. Baginsky[4] reported 525 cases of diphtheria in children treated in the Kaiser und Kaiserin Friedrich's Hospital for Children in Berlin between March 15th, 1894, and March 15th, 1895, with a fatality of 15·6 per cent. In the middle of this period, during the months of August and September, the supply of antitoxin entirely failed, with the result that the mortality rose higher than it had been before the new treatment was introduced—viz., to 48·4 per cent. The same failure in the supply of antitoxin caused a similar involuntary experiment to be carried out at Prague, Vienna, and Trieste, with the result that the fatality which fell during the period of antitoxin treatment to 12·7, 22, and 18·7 respectively, rose again during the interval when no antitoxin could be procured to 53, 65·6, and 50 per cent.[5] In the Charité, in Berlin,[6] during the eight years which preceded the antitoxin treatment the fatality rate of diphtheria was over 50 per cent., while during the 4-year period from March, 1894, to March, 1898, the rate was under 16 per cent. Moreover, although the admissions during this latter period had increased by about 50 per cent., yet the absolute number of deaths fell from 316 in 1886–90 and 308 in 1890–94 to 134 to 1894–98.

TABLE I.—*Admissions for, and Deaths from, Diphtheria in the Charité Children's Hospital, Berlin, and in all the Berlin Hospitals.*

	1894–1897	10,026	1,823	18·2

[2] Reports upon the Use of Antitoxin in the Hospitals of the Metropolitan Asylums Board, 1895 and 1896.
[3] Annales de l'Institut Pasteur, September, 1894.
[4] Die Serumtherapie der Diphtherie, Berlin, 1895.
[5] Welch, loc. cit.
[6] Kossel: Deutsche Medicinische Wochenschrift, No. 15, 1896, p. 229.

In all the Berlin hospitals[7] the percentage mortality of diphtheria, which was 35·7 in 1886–89 and 38·4 in 1890–93, fell to 18·2 in 1894–97. In 1896 and 1897 it was only 13. Moreover, in spite of increased admissions the total number of deaths for each of the three periods of four years each was 2302, 3106, and 1823. Much might be added, but enough has been said to show that the fatality of diphtheria in the hospitals of some of the great cities of the continent has very considerably diminished since the introduction of the serum treatment.

Turning now to the London hospitals we find that there has been a very satisfactory diminution in the fatality of diphtheria in the hospitals of the Metropolitan Asylums Board, and that, as already pointed out, there is no reason to attribute this diminution to any falling off in the average severity of the cases treated. I shall briefly refer to that part of the evidence as to the influence of the new treatment contained in these reports which seems to me to be least open to criticism, and for this purpose I have drawn up the following table (Table II.).

TABLE II.—*Number of Deaths from Diphtheria per 100 Case in the Metropolitan Asylums Board Hospitals, both those Treated with Antitoxin and those not.*

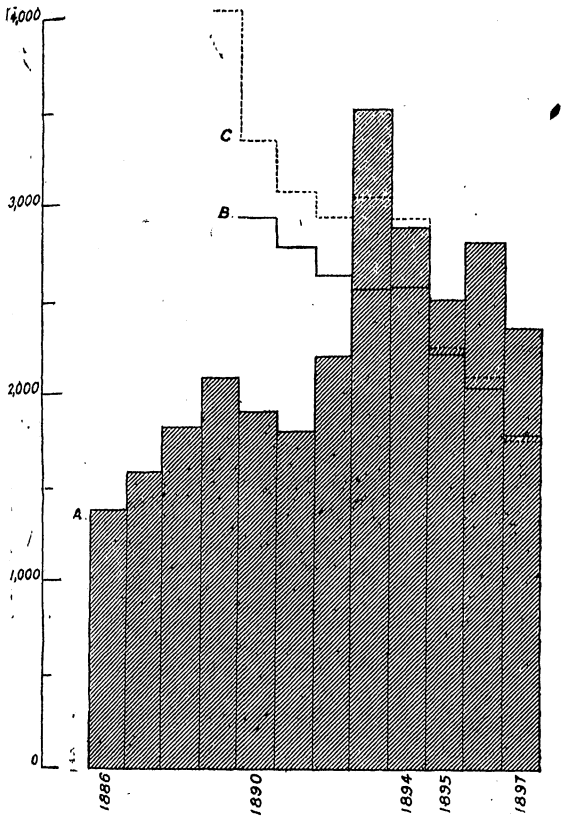
Post-scarlatinal diphtheria, laryngeal cases	60·80	—	22·7	8·4

The considerable fall in the fatality of the cases treated from the first and second day of the disease in 1895 and 1896 as compared with those treated in 1894 cannot, I think, be attributed to any other cause than the introduction of the new treatment. It is probable that the classification according to the days of disease upon which the treatment was commenced is not quite accurate. But it is certain that the treatment did not commence at an earlier period than that stated, and consequently if it were possible to correct these figures the evidence which they would then afford would probably be still more strikingly in favour of the antitoxin treatment. This is borne out by the records of post-scarlatinal diphtheria, of which the day of commencement could be accurately determined because the disease attacked patients already under observation. In 1896 the fatality of 250 of these cases treated from the first day and of 163 cases treated from the second day was 2·3 and 3·6 per cent. respectively.



The remarkable fall in the mortality of all cases of post-scarlatinal diphtheria from over 50 per cent. in the five years which preceded the antitoxin treatment to 5 and 3·7 per cent. in 1896 and 1897 respectively cannot be entirely put to the credit of the remedy, for it is admitted that the bacterial test has enormously increased the number of mild cases which are now recognised as post-scarlatinal diphtheria.[8] But the fact that the *total number* of deaths among these cases fell from over 48 per annum in 1890–94 to 35 in 1896 and 29·452 in 1897 can fairly be ascribed to the treatment, as can also the fact that the mortality of all the laryngeal cases in this group fell from 60 to 80 per cent. in the years preceding 1895 to 22·7 in 1896 and 8·4 in 1897.

The statistics of laryngeal diphtheria afford perhaps the surest evidence of the influence of treatment, for these cases form a class of which the mortality rate is but little affected by the inclusion or exclusion of a variable number of mild cases in consequence of alteration of the criteria of diagnosis. No doubt they are relatively more frequent in severe epidemics than in mild ones, yet the average severity of the cases which constitute this class remains nearly constant. It is therefore very satisfactory to find that the

[7] Ibid.
[8] Between 1890 and 1894 the average yearly number of post-scarlatinal cases was 96·4. In 1896 it had risen to 695 and in 1897 to 796.

mortality rate of all laryngeal cases has fallen 50 per cent. since 1894, that the necessity for tracheotomy is less frequent, and that the mortality rate of those cases which still require operation has fallen from 70 to 41 per cent.

But while the hospital returns of this and of other countries afford such remarkable evidence of the benefits of the antitoxin treatment of diphtheria I have all along felt that the case for the new remedy would not be complete until the annual number of deaths from this disease in great towns and other large areas should have shown a well-marked and lasting decline. I say a lasting decline because, as is well known, the annual number of deaths from diphtheria in any one area varies considerably. This is very clearly shown in Dr. Newsholme's recent work.[9] Such a decline, lasting already over three years and unprecedented in magnitude, has indeed been recently shown by figures published by the Imperial Health Office and the Municipal Statistics Office in Berlin to have occurred in Paris and Berlin and in 266 German towns of over 15,000 inhabitants each. These figures are cited by Dr. Kossel in the *Deutsche Medicinische Wochenschrift* of April 14th, 1898, p. 229. I thought it would be interesting to compare these figures with those relating to London and so I have constructed diagrams which represent the annual number of deaths from diphtheria in these places. And I have added to the diagrams for London and Berlin curves showing the number of deaths in per 10,000 notifications and the number of deaths in the hospitals per 10,000 admissions. The figures upon which the diagrams for Berlin and the other German towns are based are taken from Dr. Kossel's paper. To the Registrar-General and the medical officer of health for the County of London I am indebted for the numbers of deaths and notifications in London, and to M. Bertillon, chief of the Statistical Department in Paris, I am indebted for the number of deaths in that city. I should like to take this opportunity to express my gratitude to these gentlemen for the great kindness which they have shown in supplying me with the information which I required.

These charts show that in Paris, Berlin, and the 266 German towns there has been a remarkable fall in the annual total number of deaths from diphtheria—a fall which commenced abruptly with the introduction of the serum treatment, has steadily continued since, and has had no parallel in the previous eight years. In London, on the other hand, they show that though there has been on the whole an improvement since 1893, yet the number of deaths in each of the last three years has been greater than that of any of the seven years that immediately preceded 1893. Moreover, the case mortality in Berlin has fallen to a considerably lower point than it has in London. Indeed, the chart for London shows a marked and deplorable contrast to those of the other towns.

How are these facts to be accounted for? The following suggestions present themselves for examination:—(1) There was more room for improvement on the continent than in London; (2) the prevailing type of diphtheria has been very severe in London during the past three years; (3) the serum used in this country is inferior to that used abroad; and (4) the remedy is more extensively used there than here.

1897	3,723	546	1,947	263	1 : 1·9

1. It is true that in the years which immediately preceded the antitoxin treatment the ratio of deaths from diphtheria to inhabitants[10] was considerably higher in Berlin than in London; it is therefore certain that there was more room for improvement there than here. But, on the other hand, the Berlin rate has now fallen to a considerably lower level than our own. The same may be said of the case-fatality rates. Our present condition is therefore unsatisfactory.

2. Reference to Table III. will show that the notifications of diphtheria in the metropolitan area have more than doubled since 1890. A considerable rise occurred in 1892; in 1893 the figures rose to the alarming total of 13,694. A slight decline took place in 1894 and 1895, but again in 1896 and 1897 the figure has been over 13,000. In Berlin, on the other hand, the number of notifications has been more constant (Table IV.). But while the great prevalence of the disease in London in recent years may explain why the annual numbers of deaths from diphtheria there have not diminished as in Berlin it does not account for the difference in the fatality rate of the affected in the two cities.

3. In 1896 THE LANCET Special Commission on the Relative Strengths of Diphtheria Antitoxic Serums[11] reported unfavourably of the serums prepared in this country: have they improved since that time? I have personal knowledge that some at least of the antitoxin used as recently as the first half of last year, and coming from more than one London laboratory, had very much less antitoxic power than that claimed for it.[12] But the methods of preparing the serum and of estimating its strength have improved since then, and we have it on the authority of Dr. Sims Woodhead[13] that the average strength of the serum now issued from the laboratories of the two Royal Colleges is 375 units per c.cm. If, then, our comparative ill-success has been due in part to the weakness of our antitoxin we may look with some confidence for better results in the near future.

4. But if our antitoxins have been weak, is this the sole reason for our comparative ill-success? Or is it partly due to the remedy being more freely used in Berlin than in London? We may, I think, assume that in our hospitals the antitoxin is used about as freely as it is in those of Berlin. And it is shown by the charts that the fatality rate of all cases goes closely hand in hand with that of the hospital cases only both in Berlin and London. It is therefore at first sight tempting to conclude that the remedy is used to an equal extent by the private practitioners of the two cities as it is by the hospital physicians.

On further consideration, however, I think this reasoning is unsound. For in Berlin, where the fatality rate of diphtheria prior to 1893 was very high, and where the hospital rate was in that year no higher than that of the whole city, the introduction of the new treatment was followed by a

[10] See Dr. Newsholme: loc. cit., pp. 30 and 75.

[11] Report of THE LANCET Special Commission on the Relative Strengths of Diphtheria Antitoxic Serums. THE LANCET, July 16th, 1896.

[12] The majority of the estimations were made by Ehrlich's old method, but several were repeated, using the new method and a standard toxin sent by Professor Ehrlich himself. These showed that the original estimations were substantially correct.

[13] Report of the Council of the Royal College of Surgeons of England, October, 1898.

Digitized by Google

remarkable fall both in the general and in the hospital rate. In London, on the other hand, where, prior to 1894,[14] the fatality rate of diphtheria was steadily improving and where the rate for the whole city was considerably lower than that for the hospitals alone, the introduction of the new treatment was followed by a fall in the hospital rate, which then came to coincide with that for the whole city; but the latter was scarcely affected and continued to follow the direction of its previous course. It would even appear that the improvement in the case mortality of diphtheria in London has been due to other causes than the new treatment. On the other hand, the enormous fall in the case mortality of Berlin which took place in 1894 and 1895 cannot, I think, be attributed to anything else. And unless our serum has been entirely worthless, which is certainly far from the truth, one can only conclude that it has not been used in London to anything like the extent it has in Berlin.

Can anything more be done to improve the deplorable fatality of diphtheria in London? I think that without doubt much might be done to diminish the prevalence of the disease by the isolation of convalescent patients until bacterial examination of the throat showed the absence of the Klebs-Löffler bacillus. Not many months ago I was asked by the house physician in one of our provincial hospitals to examine a child and report as to his fitness to return home. A day or two later I reported that virulent diphtheria bacilli were still present in the throat, whereupon the house physician replied that the child had already gone home, as he could not wait for the result of my examination. I fear that this is no isolated instance. No doubt if the patients were not sent home until the bacillus diphtheriæ could no longer be found in their throats, in some instances children would have to be isolated for several months. But even so that would be cheaper—to put it on the meanest grounds—than allowing them to go home and spread the seeds of the disease.

The fatality rate of diphtheria within the hospitals both in London and Berlin used to be considerably greater than of cases treated in their own homes, and this is not surprising, seeing that it is only the severer cases and often the moribund which are brought to the hospitals. But on the introduction of the antitoxin treatment the hospital fatality rate fell as low as the general rate in Berlin, even a little lower. This, I think, indicates that both there and here the new remedy has been more readily adopted by the hospital physicians than by general practitioners, and affords grounds for the hope that when the latter become fully alive to its advantages the fatality rate of private cases may fall and become as much better than that of the hospital cases as it was in former years. By many medical men I fear the antitoxin is looked upon as being in an experimental stage. They do not recognise that they possess a remedy which is capable of robbing diphtheria of its terrors, the evidence as to the utility of which is such that those incur a grave responsibility who do not use it. Called into a case they too often trust that it will be a mild attack and hesitate to apply the means of cure until it is too late. The parents of the little patients are in the majority of cases ill-informed, and either do not know of the remedy or look upon it as a dangerous substance obtained from a diseased animal and consequently they do not call for assistance until they are seriously alarmed. It is scarcely too much to say that if these ignorant people could be induced to bring their children for treatment as soon as the first symptoms of disease appear, and if the medical men would make thorough use of the remedy, the greater part of the mortality of diphtheria would disappear.

Cambridge.

[14] The influence of the new treatment is shown in the Berlin returns for 1894. But in London it can scarcely be said to have commenced before 1895.

ISOLATION HOSPITALS IN GLAMORGANSHIRE.—At a meeting of the Isolation Hospital and County Laboratory Sub-committee of the Glamorganshire County Council held at Cardiff on Nov. 22nd plans were approved for isolation hospitals at Pontardawe and in the Rhondda Valley. Mr. T. H. Morris, M.B., C.M. Glasg., Alderman R. W. Jones, M.B., C.M. Glasg., J.P., and Mr. H. N. Davies, L.R.C.P. Lond., M.R.C.S. Eng., were appointed commissioners to inquire into the proposed establishment of an isolation hospital for Penarth. Dr. Morris and Dr. Jones were appointed a sub-committee on the question of fitting up the chemical section of the county laboratory.

THE

INOCULATION THEORY OF MALARIAL INFECTION.

ACCOUNT OF A SUCCESSFUL EXPERIMENT WITH MOSQUITOES.

BY DR. AMICO BIGNAMI,

PHYSICIAN TO THE HOSPITAL OF SANTO SPIRITO, ROME; UNIVERSITY LECTURER ON PATHOLOGICAL ANATOMY.

IN a former article on Hypotheses as to the Life-History of the Malarial Parasite outside the Human Body[1] I expressed the opinion that an investigation of the mechanism by which the parasites penetrate into the blood of man ought to be the first step which would lead with certainty to a knowledge of the extra-corporeal phase of these hæmatozoa. I therefore reviewed afresh the old controversy as to how the fever is contracted, examining the various hypotheses most generally held, to show which of them is most in harmony with the best ascertained facts regarding the epidemiology and pathology of malaria. The theories most discussed were, and still are, those which regard as the vehicles of infection air and water respectively. With respect to the water-conduction hypothesis, I reviewed the theories and facts which Laveran, its principal supporter, adduced in its favour and showed how it can no longer be sustained after the experimental investigations of Celli and various other observers and especially in view of our experience of many malarious places in the Roman Campagna, where water of the same excellent quality is drunk as in perfectly healthy places in their immediate neighbourhood. I may add that the greater number of recent observers who have studied malaria in the most diverse parts of the world attach no value in their own experience to water as a vehicle of infection.

It was a more difficult matter to dispose of the air-conduction theory. Of all infectious diseases there is none whose origin from, or at least close connexion with, the soil is more generally admitted by epidemiologists than that of malaria. Now, in regard to the hypothesis that the malarial parasite exists in a free state and resists desiccation so as to be breathed with the atmospheric dust, I pointed out that *malaria does not comport itself in the least degree like a disease due to the inhalation of dust*. And apart from this I showed that the theory of the passage of germs from the moist earth to the "ground air" ("grundluft") has various difficulties to encounter which are not easily surmounted. Other difficulties which I noted which the supporters of the air-conduction theory had to contend against lie in explaining why malaria is not transported by the wind or, at least if it be so transported, why the fact is of no practical importance in the diffusion of the disease; and why the malarious load carried by the atmosphere should vary notably at different hours of the day, &c. And I contended that those who accepted the view that malarial germs pass from the soil into the air could offer only artificial and inadequate explanations of these and other facts. From this I passed to an exposition of the hypothesis of inoculation, asking myself whether this theory agreed with known facts regarding the diffusion of the fever and the conditions which favour the contracting of it. I pointed out that, granted the truth of this hypothesis, the explanation of many of the facts which are difficult to understand in the air-conduction theory becomes at once easy and satisfactory. Thus, if it be true that malaria is inoculated on man by the agency of mosquitoes it is not difficult to understand why, for example, it is not transported by the wind; why the hours of evening and of night are most dangerous for contracting it; why the infection does not extend in the vertical direction excepting to slight altitudes; and why it should be dangerous to sleep in a malarious locality. I cited finally some observations which proved the utility of mosquito curtains in malarious localities. Taking into consideration these and other facts, which are here omitted for the sake of brevity, I arrived at the conclusion that "malaria behaves itself with regard to man as if the malarial germs were inoculated by mosquitoes."[2] I omit, likewise for brevity's sake, to refer in detail to what I supposed to be the relations existing between malarial parasites

Digitized by Google

and mosquitoes. But I wish to recall the fact that I laid great stress upon, and attached great value to, one argument in favour of the inoculation theory—viz., its analogy to the cattle fever of Texas, in regard to which the beautiful experiments of Smith and Kilborne were already known.

That mosquitoes might in some way be connected with the life-history of the malarial parasite had already been surmised by various authors. But with the exception of a few of the most recent these writers all looked upon the mosquito as acting the same part in malaria as it does in filaria disease and not as an inoculating agent. Thus Laveran, in his celebrated "Traité des Fièvres Palustres,"[3] at page 457, after having stated that he had repeatedly examined the water of malarious places and had several times found motile filaments very closely analogous to the microbes present in the blood of malarial patients, but that he had never in this search encountered pigmented elements analogous to the cystic bodies No. 1 and No. 2, goes on to say: "It is easily understood that the microbes of malaria may be encountered in the blood in forms which may differ considerably from those which they present in the outer world. The natural history of parasites offers us numerous examples of such transformations. I shall restrict myself to recalling the curious facts which have been discovered during the last few years in regard to filariasis. The filaria embryos which are found in the blood of those affected by this disease make their way into mosquitoes with the blood which these insects suck up from individuals suffering from filariasis. In the body of the mosquito they undergo a transformation, and when the latter eventually dies on the surface of some stream the filaria make their escape into the water and are subsequently swallowed in drinking-water by man. Has the mosquito a similar *rôle* in the pathogenesis of malaria to that which it has in that of filariasis? The thing is not impossible, and it is a noticeable fact that mosquitoes abound in all malarious places." These are the actual words of Laveran,[4] who then goes on without absolutely excluding the air-conduction theory to bring together and discuss facts which in his opinion support the hypothesis that malaria is contracted through drinking the water of malarious places.

In all this there is not the slightest hint at the theory of inoculation, nothing but a speculation as to the possibility that the mosquito has the same relation to malarial parasites as it has to the filaria nocturna; in other words, we have here something of the same kind as the theory of Manson, but nothing whatever of the theory which I have expounded above. Laveran expresses himself in the same way in the edition of his book of 1891. In an article published in 1896[5] he relinquishes the water-borne theory, since he observes that whilst many facts go to prove that infection may be brought about by drinking-water, yet none of these facts are absolutely demonstrative, and he states that the mosquito theory tends to gain ground as being that which better accords with what we know of the circumstances in which malarial infection may be contracted. In the last edition of his book (1898) Laveran alludes to the hypothesis of inoculation.[6]

The article of Manson[7] is very well known, in which he revives in the main the hypothesis of Laveran, contending that mosquitoes comport themselves with respect to malaria in the same manner as they do with regard to filariasis. Manson, in order to give a rational basis to his conception, avails himself of his extensive parasitological knowledge and formulates the hypothesis that the flagella of the so-called malarial flagellates are the forms which, developing in the bodies of mosquitoes, there commence the extra-corporeal life-cycle of the malarial parasite. Thereupon the mosquitoes, dying in the water, sow it, so to speak, with malarial germs, and the water in this way becomes the carrier of the malarial infection to man. Also in a recent work[8] he upholds the idea that man becomes infected by drinking water contaminated by mosquitoes or through the medium of inhalation.

I will not revert here to the criticisms which I have already made upon this view of Manson, who at any rate has the merit of having prompted and guided the extremely interesting researches of Ross. While these researches were still going on Dionisi,[9] in our laboratory, observing pigeons infected with the halteridium-Labbé (or *Laveranie*-Grassi), advocated the inoculation theory as the most plausible explanation of the infection, since the birds became infected as a rule after moulting, when they were vulnerable to the bites of mosquitoes. Ross, working in Calcutta, succeeded in determining the phases of the life-cycle of proteosoma from sparrows and other birds infected through bites by a particular species of mosquito (grey mosquito).[10] These hæmatozoa having entered into the stomach of the grey mosquito develop into forms which Ross considers as coccidia (proteosoma-coccidia); in the mature coccidia "germinal rods" are formed which find their way to, and collect in, the veneno-salivary glands of the insect which at this point becomes capable of injecting the proteosoma with its bite into healthy sparrows.

After these most interesting observations of Ross on the biology of the parasites of birds, Manson, who communicated them to the recent Congress at Edinburgh, admits that the malaria of man may also be inoculated by mosquitoes, but without maintaining that this is the only possible mode of infection.[11]

Quite recently the theory of inoculation has found a further supporter in R. Koch[12] who has been studying malaria in the German colony of East Africa and who puts forward the hypothesis that the malarial parasites have the same relation to the mosquito as the parasites of the fever of Texas have to the cattle-tick. He does not, indeed, add any new fact in its favour, but it will be attributable to the great authority of this writer if the theory of the inoculation of malaria by means of mosquitoes has become more widely known and has gained more credence among us during the present year. Of the very interesting observations of Grassi[13] on the same subject I shall have occasion to speak several times further on.

In 1894—i.e., nearly three years before the publication of my paper in THE LANCET—I made some experiments with the object of finding whether my hypothesis of inoculation would withstand the test of facts. In these experiments I had Dr. Dionisi as my co-worker. They did not succeed because for want of means we could not secure for them conditions similar to those in which infection is contracted naturally. And to this explanation adopted by myself another may be added (as Dionisi remarks)—namely, that in all probability among the species used by us those by which the natural infection is carried were not represented (*loc. cit.*). For these reasons I do not believe that the negative result of the experiment ought to discredit the value of the hypothesis.

In resuming the experimental study of this question I had to consider two ways by which it might be approached. In the first place, I might make use of an indirect method of investigation, carrying out experiments in some locality of a highly malarious character on a large number of individuals all living under similar conditions. Of these, one portion would be protected in some way from the bites of mosquitoes, especially at night, while the other portion would be left undefended like the ordinary inhabitants of the place. Such protection might be afforded by thick mosquito nets, by providing the windows of sleeping apartments with frames covered with gauze, and also by means of fumigation, for which purpose the smoke of ordinary wood is known to be efficacious. The effect might likewise be tried of anointing the body with aromatics, as the ancients were in the habit of doing and as some tribes living in tropical climates still do, apparently with the object of defending themselves against the bites of these insects. All possible precautions having been adopted towards securing that end it would then be seen whether the protected persons were preserved by this means from attacks of fever. But this way of solving the question I was obliged to abandon for want of sufficient means and

Digitized by Google

on account of the great difficulty of maintaining rigorously the conditions of the experiment. It would, in fact, have been necessary to have had a certain number of men entirely at one's disposal, to have exercised a rigorous and continuous surveillance over them, and to have obtained the consent of a portion of them to submit to the measures indicated above. Now, anyone acquainted with the population, so largely nomadic, of the Roman Campagna can easily imagine how difficult it would be to attain the desired end under such conditions. I therefore applied, with the support of Professor Celli, to the military authorities, proposing that the experiment should be carried out in the forts surrounding Rome, many of which are situated in localities highly malarious. It is well known that many of the soldiers who man these forts fall ill from fever from the month of July onwards. Now, I proposed that one part of the troops should remain shut up from sunset till morning in dormitories protected against the entrance of insects—an easy matter, one would suppose, to arrange—whilst the other part should be left under the habitual conditions. If, then, let us say, some of the men who had been left to follow their ordinary habits took fever while none of those who had been protected from mosquito bites were affected (the other conditions of life being identical for both) we should have obtained an indirect demonstration of the way in which the fever is contracted. But unfortunately, for reasons connected with the military service, it was not possible to carry out such an experiment.

In the second place it was open to me to try afresh the direct method of investigation, modifying in various ways the conditions of the experiment. I have already recorded the negative result which attended the first experiments instituted by me in 1894 at the Hospitals of Santo Spirito and San Giovanni. These were made with a large number of mosquitoes captured on the estate of Porto, near Fiumicino (a highly malarious locality), and set at liberty in rooms specially prepared for the purpose. The non-success of this experiment was due, I consider, to the fact that the conditions under which it was carried out were too dissimilar in the subjects experimented upon to those under which the fever is contracted naturally. It is well known, indeed, that mosquitoes have but a brief existence; hence it is necessary, in order to keep the individual in what I may be allowed to call an *artificially malarious* environment, that the supply of these diptera should be renewed very frequently. Again, it is an ascertained fact that only exceptionally do persons exposed for only a short time to the infection contract the fever even in the most highly malarious localities and that in general a sojourn of at least a week or two weeks in such a locality is necessary. Not having at the time any person at my disposal suitable for such a purpose, and not possessing the means of procuring one, I could continue the experiments for only a very short time. As the mosquitoes collected in my first experiments were naturally representative of the species most prevalent in the malarious locality from which they were taken, I shall be correct in saying that these experiments were carried out in precisely the same way as the latest ones to which I am now about to refer, and the result of which has been to decide this question. The sole difference between the first unsuccessful experiments and these last consists in this—that the first for want of sufficient means were too soon interrupted.

It was clear, then, that in making a fresh attempt this year to solve the problem, I must assimilate the conditions of my experiment as nearly as possible to those natural ones under which the fever is usually contracted. It was further necessary, in order that the result should be positively demonstrative, to surround the experiment with the greatest precautions and with this in view to carry it out in an environment known for certain to be non-malarious, where no one had ever contracted the fever; to employ for the purpose an individual who had never had malaria and who had been in the hospital for as long a time as possible under medical supervision; and to continue the experiment for several weeks and during this period to renew rather frequently the supply of mosquitoes. It will be easily understood that it was no easy matter to satisfy with certainty the first of these conditions; it was more especially difficult to find anyone in the circumstances indicated willing to allow himself to be subjected to the test. And, given all this, it must not be forgotten that the persons experimented upon are placed in conditions much less favourable to the contracting of disease than are the inhabitants of the Campagna. Everyone knows how important are good food, a regular, tranquil life, and the avoidance of over-exertion in warding off the fever even in highly malarious places, and how much less frequently persons living under such conditions are attacked than those labourers who are badly fed and overworked and exposed to a broiling sun and to inclement weather—in short, to all those causes which favour the development of infection. Thus, even supposing that the subjects of my experiments had been inoculated with malaria, it is conceivable that in the conditions under which they were placed they might be able to resist the development of the infection in virtue of good nourishment, rest, and the absence in general of circumstances unfavourable to health. If it is further taken into account that there are individuals who enjoy a natural immunity from malarial infection it will be conceded that a negative result could not be looked upon as conclusive evidence against the theory, whereas a positive result obtained under the conditions indicated would have the force of a complete demonstration.

My last experiments were commenced in the beginning of August of this year. They were carried out upon three individuals, with various modifications which will be described later. A small room of two beds was selected on the second floor of the Hospital of San Carlo (near Santo Spirito), in connexion with the section under my charge. Its two windows having been closed with frames covered with gauze, adult mosquitoes brought from a malarious locality were set at liberty or receptacles containing larvæ of mosquitos collected in the Campagna were placed in it. The persons selected all submitted themselves voluntarily to the experiment after I had clearly explained to them what I wanted to try. They were shut up in the "mosquito chamber" in the evening a little before dusk and were kept there all night. In the morning they came out and passed the day in the ordinary wards.

(To be continued.)

FUNCTIONAL DYSPHAGIA.[1]

BY STCLAIR THOMSON, M.D., M.R.C.P. LOND., F.R.C.S. ENG.,
PHYSICIAN TO THE THROAT HOSPITAL, GOLDEN-SQUARE; SURGEON TO THE ROYAL EAR HOSPITAL, LONDON.

PHYSIOLOGY OF DEGLUTITION.

DEGLUTITION is the muscular movement by which liquids and masticated boluses of food are transmitted from the mouth to the stomach. It might be well, as a preliminary, to briefly recall the physiology of the process. Although the passage from the mouth to the stomach is one continuous and uninterrupted movement, still, for convenience of description, it has been divided into three acts. In the first act the masticated food is gathered up into a bolus in the mouth, and then (chiefly through the action of the tongue) pressed backwards past the anterior arch of the fauces. In the second act it is grasped by the constrictors of the pharynx and passed downwards over the entrance to the glottis until it reaches the œsophagus, when the third act begins, to terminate on the entry of the food into the stomach. This third act is very rapidly performed, as may be observed in animals with thin necks, such as the swan, in whom a rapid ripple in the situation of the gullet indicates the rate of transit. The first act is voluntary, although usually performed unconsciously. It is carried out by the muscles of the tongue and palate, chiefly the former. In the second act the muscles of the anterior faucial pillars contract on the morsel, and then behind it, so as to shut off the return to the mouth; the soft palate and posterior faucial pillars bar the route to the posterior nares; the entrance to the glottis is protected by the contraction of its own muscles, and by the tongue being retracted while the larynx is lifted with the pharynx and carried forward beneath its base. At the same time the pharynx is raised to receive the food when it, in its turn, contracts, and so the bolus is passed downwards till it enters the œsophagus. The point of separation between the pharynx and œsophagus is purely an arbitrary one. The upper third of the latter tube is composed entirely of striped voluntary muscle fibres, and the

[1] A paper read before the Harveian Society of London on Nov. 17th, 1898.

Digitized by Google

level of the cricoid cartilage is simply chosen as a convenient situation to draw a boundary line between them. Arrived at this point the tonic contraction of the circular muscles is relaxed, and the food leaves the pharynx to enter the peristaltic grip of the œsophagus, which, as already observed, rapidly passes it on to the stomach. In this process "if we suppose the bolus to be at one particular place in the tube," as Halliburton well remarks, "it acts stimulatingly on the circular muscular fibres behind it and inhibitingly on those in front; the contraction therefore squeezes it into the dilated portion of the tube in front, where the same process in repeated and this travels along the whole length of the tube.[2]

INNERVATION OF DEGLUTITION.

The first of the three acts of swallowing is entirely a voluntary one. The second and third acts are involuntary. This refers, of course, to a physiological condition; we shall have occasion to see that volition has a certain amount of control during the second part. The nerve centre, coördinating the action of the muscles employed in the second and third acts, is situated in the medulla oblongata. In the reflex portion of the act the following nerves are concerned: *sensory* or afferent, branches of the fifth supplying the soft palate; glosso-pharyngeal, supplying the tongue and pharynx; and the superior laryngeal, supplying the epiglottis and larynx. The *motor* fibres concerned are: branches of the fifth, supplying part of the digastric and mylo-hyoid muscles, and the muscles of mastication; the glosso-pharyngeal, supplying the muscles of the pharynx; the vagus, supplying the soft palate, and the muscles of the larynx through the inferior laryngeal branch; and the hypoglossal, the muscles of the tongue. With regard to the œsophagus the nerve structures concerned are the ganglia contained in its walls and the pneumogastrics. These nerves supply the gullet with motor branches and act as inhibitory on the tonic sphincter at the cardiac extremity. When they are divided therefore the cardiac end remains firmly contracted, while the œsophagus becomes paralysed, and if food is swallowed it accumulates in the gullet and does not arrive at the stomach. As in the peristalsis of the intestines, the motor property of the muscle of the œsophagus is an inherent property in it, although controlled by nervous agency. Hence if the gullet is cut across leaving the nerve branches intact a wave of contraction will travel from one end to the other across the solution of continuity.

With regard to the swallowing of liquids it has been shown by Kronecker that the act of deglutition is differently produced and that its division into three stages is true for solids only. A mouthful of liquid is, in fact, projected from the mouth into the gullet by a sort of force-pump action of the two mylo-hyoid and hyo-glossi muscles. These muscles combine to pull the base of the tongue first upwards and backwards and then backwards and downwards. In this way the pharyngeal muscles hardly contract on the liquid at all. These preliminary considerations as to the mechanism of deglutition will find their application in many points which will present themselves in the course of this paper. True paralysis of the œsophagus is very rare. It is most often due to central disease—cerebral tumour, bulbar paralysis, or general paralysis of the insane. It is sometimes peripheral and due to diphtheria.

FUNCTIONAL DYSPHAGIA.

Functional dysphagia may be manifested under two forms—a paralytic and a spasmodic. There is either a difficulty in passing the bolus of food (which for brevity we may refer to henceforth as "the morsel") from the mouth into the pharynx or else the morsel cannot be passed from the pharynx into the gullet and is, as a rule, rejected. Once the food passes the level of the cricoid cartilage there is generally no functional affection which arrests its passage downwards to the stomach. One might imagine a condition of "œsophageal constipation" from muscular atony, but I do not know if it has ever been demonstrated. A form of spasmodic stricture of the gastric extremity of the œsophagus has been described by Dr. J. C. Russel of Southport.[3] This appears to occur at all ages and in both sexes; it is not markedly associated with what we understand as hysteria and neurasthenia, and the two chief symptoms are dysphagia and vomiting, and the bougie will sometimes, but not always, detect a spasmodic stricture of the cardiac end of the gullet. The condition is often ascribed to some affection of the stomach, and Dr. Russel considers that dilation of the stricture with bougies is not sufficient—it should be stretched by an expanding dilator.

Functional dysphagia is not necessarily associated with the affection known as "anorexia nervosa," so well described by Sir William Gull. There is sometimes a loss of appetite for solid foods, but as a rule no distaste for it. In the first form of functional dysphagia the patient is able to masticate food thoroughly but appears unable to gather it into a bolus and pass it through the anterior pillars of the fauces. This, strictly speaking, can hardly be termed difficulty of swallowing; frequently no attempt at all is made to swallow; there is often no complaint of pain; the patient simply states her inability to get the food out of her mouth. It might more correctly be termed "aphagia." Before they come under observation these patients—the majority of whom are females—have given up every idea of even making the effort to swallow solids and have nourished themselves entirely on liquids. If they can be induced to attempt the deglutition of some solid food it will be observed that the first step of the first act is made with an effort which, in the absence of local symptoms, is too palpably overdone. The lips are too firmly compressed, the jaws too steadfastly clenched, the chin is pushed forwards and the head appears to sink to meet the rising pharynx. Still the morsel may exit from the mouth, but it will be noticed that the second stage of deglutition does not follow quickly, the raised pharynx does not sink down again as it should do when the food passes from its grasp, and the patient retains her head in a fixed position, while her face shows an anxious and expectant expression. Generally within a few seconds and with a gulping action the bolus is returned into the mouth or shot out straight through it, while the patient looks relieved, or martyrised, or complacent—or all three! This gulping action is not unlike that which one sees in a dog when, being pursued or from other causes which demand despatch in eating, it tries to bolt a half-masticated piece of food. Finding that it will not pass the cricoid cartilage the animal gulps it back into the mouth for further trituration. In the condition I have been describing, however, the dysphagia is not due to any undue bulk in the bolus; it is caused by the second of the two forms of functional dysphagia—in other words, by spasm of the upper constrictor of the œsophagus. This latter is frequently referred to by the title of "œsophagismus," but I think it might be a good plan to bear in mind that although one form of functional dysphagia is associated with œsophagismus, still this latter term is also applicable to the spasm of the gullet which may occur in the course of certain nervous disorders, such as chorea, epilepsy, hydrophobia, and tetanus. Œsophagismus may result from long-continued or violent retching, and it may be associated with an early stage of malignant disease of the œsophagus. It might therefore be advisable to avoid the use of the term when we mean functional spasm and to limit "œsophagismus" to the above nervous conditions and to that met with in pseudo-hydrophobia, in reflex spasm from causes situated in the gullet itself (foreign bodies, &c.), or at some distance (the base of the tongue, the pharynx, teeth, nose, ear, stomach, &c.), or due to general affections, such as gout.

ETIOLOGY.

Functional dysphagia is therefore an affection which may be paralytic, or spasmodic, or both. The starting point is not infrequently some form of sore-throat, the temporary lodgment of a foreign body in the pharynx, or some other occurrence which attracts the patient's attention to her power of swallowing. Or it may date from some mental or physical strain, prolonged lactation, recovery from acute illness, &c. As already mentioned, the large proportion of sufferers are females and it is said to occur in those of a neurotic type between the ages of nineteen and thirty. But I have come across it in females of almost any age—a most typical case occurred in a young man aged eighteen years—and cases have been met with in children. Undoubtedly it is met with most frequently in those of an hysterical temperament, but it is very difficult to detect a history or stigmata of hysteria in those who apply for this condition, for this trouble is rare in old-standing hysteric cases (Weir-Mitchell) and when it occurs it is frequently amongst the first hysterical symptoms complained of. There are certain symptoms of hysteria which appear early in that disease, just as there are others which do not show themselves as a rule till the later

[2] Kirkes' Handbook of Physiology, fourteenth edition, 1896.

Digitized by Google

stages. As Weir-Mitchell puts it, "Dysphagia one sees often in cases which are afoot."[4]

DIAGNOSIS.

The patient may therefore present herself before her hysterical character has been revealed, and her condition enlists so much sympathy and the diagnosis is sometimes so difficult that its differentiation from much more serious affections is not always readily arrived at. It is a very different affair, for example, from functional aphonia, where not uncommonly there is a history of previous attacks of sudden loss of voice with sudden recoveries, and a glance with a laryngeal mirror settles the diagnosis. In functional dysphagia our suspicions may be aroused if the patient states that she "cannot get the food out of her mouth," or if she states that "it goes down but comes up again before it is half swallowed," or that "when she goes to swallow she feels a ball rising in the throat to meet it." The patient may also present herself without any loss of weight, being able to nourish herself on liquid food. In other conditions of dysphagia the amount of liquid nourishment taken is not always compensatory. In malignant disease, for example, the sufferer may be able to swallow a much larger amount of liquid nourishment than another patient with functional dysphagia, but the latter may remain plump while the former wastes steadily. Still, many cases of functional dysphagia do become remarkably thin, but then the observer is at once struck by the fact that, as a rule, they are, as Weir-Mitchell says, not only "afoot," but though frequently pale they are not cachectic, they have no secondary affections and are able to get through a considerable amount of work. A patient with a similar amount of wasting from malignant disease would not only have the undoubted look of cachexia, but probably be too weak to leave his room. The history may be of assistance, as revealing a longer duration and arrested wasting when the dysphagia is functional, whereas in malignant disease the loss of weight is only too steady and rapid. Very few cases of malignant disease of the œsophagus last more than a year; in well-marked instances a short three months will often bring the relief of death to the sufferer. Carcinoma is rare before the age of forty years, though it sometimes occurs in early life. It is much more frequent in men than in women, in whom the proportion is between 14 and 29 per cent. of all cases; but the diagnosis is made difficult from the fact that when malignant disease does occur in early life it is chiefly met with in females.

Functional dysphagia may be associated with organic disease just as we meet with functional aphonia with pathological changes in the larynx, and of course the diagnosis is then rendered more difficult. But in an uncomplicated case there are a large variety of affections which might occur to the mind and which must be excluded before a positive diagnosis is arrived at. Many of these possibilities can promptly be considered and ruled out of court if a thorough inspection is made of the pharynx and larynx. Sir Felix Semon has pleaded for the imperative necessity of a thorough larnygoscopic examination in all cases of persistent hoarseness in patients over forty years of age so as to be prepared for the possibility of an early diagnosis of laryngeal cancer. He has also pointed out the necessity of careful inspection of the throat as a first step in dealing with a foreign body impacted in the upper air or food passages. The same pleas apply to the condition under consideration, and it is to be hoped that the time is fast approaching when neither a diagnosis nor an attempt at treatment will be meditated before a thorough direct observation has been made. Perhaps this applies particularly to children, who frequently give us little help in localising their symptoms. The rare condition of congenital atresia should be borne in mind when dealing with infants. Thrush may in infants spread from the mouth to the gullet and so give rise to dysphagia. Retro-pharyngeal and peri-œsophageal abscesses have to be borne in mind. It is not uncommon for children while holding some toy in their mouths to swallow it and never mention that it has disappeared from their buccal cavity—inwards and not outwards. In any suspected case of foreign body in a cavity the Roentgen rays have proved of the greatest value, not only in diagnosis, but in assisting treatment by localising the point of impaction.

Turning to adult patients, diphtheria may in them, as well as in children, lead to a paralysis of the soft palate and so to dysphagia by reflux of liquids through the nose. Diphtheria may also attack the gullet and the presence of membrane lead to dysphagia. Cases might not infrequently be put down as functional were a careful examination neglected. I have seen such a diagnosis made when the actual cause was a commencing epithelioma at the base of the tongue deep between its margin and the infra-tonsillar region and only visible with a laryngeal mirror. The characteristics of quinsy and other tonsillar affections are so obvious that they hardly present themselves for diagnosis. But a careful inspection of the base of the tongue and of the larynx is most important, the latter particularly if there is any alteration in voice. Acute inflammation of the lingual tonsil is sure to attract attention to the region by the severity of the symptoms; but other less-marked conditions might escape detection if not particularly looked for. Hypertrophies and enlarged veins at the base of the tongue have been credited with being the original points of irritation of functional dysphagia and a cure has been attributed to their direct treatment, generally with the galvano-cautery. The connexion between the two is not satisfactorily established and the same result might have been obtained by any other manipulation which would impress the patient. Malignant disease of the larynx is another possible point of diagnosis which may be ruled out of court by the use of the laryngeal mirror; and still more likely is laryngeal tuberculosis from its frequent occurrence between the ages of twenty-five and thirty-five years. It is not at all uncommon for foreign bodies to get lodged in the naso-pharynx and for the patient to complain only of dysphagia and refer all his symptoms to the front of his neck. I once had to treat an old gentleman, aged seventy years, who came complaining of difficulty of swallowing, slight alteration of voice, and pains shooting up to both ears. Nothing was to be seen in his pharynx and larynx, and such symptoms at his age naturally aroused the suspicion of a malignant affection of the œsophagus. The routine of examination directed me to inspect his post-nasal space, and in the site of election was a distinct syphilitic gumma the heritage of an infection of fifty years previously. Suitable treatment brought relief in a few days and within a month he was free from all symptoms.

Inspection of the larynx is of importance, not only as it may reveal the actual cause of the dysphagia, but also because it may point to pathological changes more remote. I refer to the paralysis of one of the vocal cords—or more rarely of both—from pressure of an aneurysm on the recurrent laryngeal nerve, or from involvement of the nerve in a cancer of the œsophagus. This condition is sometimes suggested by the peculiar voice of "phonative waste" which is heard when one cord is affected. This is apt to disappear when the unimpaired cord takes on increased action and crosses the glottic space to meet with the fixed cord. Those who are not expert with the laryngoscope can often, however, make a very thorough exploration of this region with the forefinger, which can be readily swept over the base of the tongue down round the rima glottidis, behind the arytenoids to the entrance to the gullet and even be carried over the ventricular bands and vocal cords. The whole post-nasal space and the posterior choanæ can be examined in the same way. Next to careful inspection of the upper air and food passages the diagnosis may be facilitated by examination of the neck. It seems almost too elementary to refer to such a matter, but the fact remains that a complete exploration of the interior of these cavities will often be made, and an observer will sometimes neglect to see if there is an enlarged thyroid pressing on the gullet. Much of the dysphagia of acute illness, fever, &c., is due to mere dryness of the mucous membranes. In some instances it is consequent on the mouth-breathing which results from the nasal catarrh and obstruction connected with many specific fevers.

Coming now to affections which are beyond the ken of the frontal mirror we have to refer to some affections of the œsophagus. In chronic œsophagitis, according to Mackenzie,[5] the dysphagia "is constant, whilst in spasm it varies to some extent from day to day, and even from meal to meal. The most important point of distinction, however, between these two affections is that whilst in spasm solids or semi-solids can often be swallowed with comparative ease in simple chronic inflammation liquids pass down much more readily." This distinction does not appear to be very well marked. The diagnosis may be based

[4] Diseases of the Nervous System, Philadelphia, 1881. p. 203.

[5] Diseases of the Throat and Nose, vol. ii., 1884.

Digitized by Google

on the general features of the case and on the fact that in functional dysphagia the difficulty is met with in the first and second acts, while in chronic œsophagitis it is the third act which is painful, and it is more a case of odynphagia than of dysphagia.

The rare conditions known as acute catarrhal œsophagitis and phlegmonous inflammation of the œsophagus may cause dysphagia, but they can readily be distinguished by the acuteness of the symptoms, the pain on speaking and even on moving, the tenderness on pressure, and other symptoms of local inflammation. Psilosis or sprue may give rise to dysphagia, but then it is only met with in Europeans who have resided in the tropics. Traumatic œsophagitis may arise from swallowing boiling water, solutions of strong alkalies or acids, or from inhaling steam. The immediate dysphagia may be recognised by its acuteness and by the history or by the stains on the lips. The secondary dysphagia resulting from the subsequent cicatricial contraction may not in mild cases set in until some months after the accident, and even after an interval during which swallowing was normally performed. In the absence of information as to the original traumatism suspicion may be aroused by the cicatrices on the lips or in the mouth. It will be noted that I do not suggest looking for any stains or cicatrices in the pharynx, and their absence is explained by reference to the introductory remarks in which it was pointed out that liquids are, so to speak, "shot" through the pharynx without coming into contact with its walls. Tuberculous disease of the œsophagus is too rare an affection to detain us. In syphilis we must depend chiefly on other signs of the disease and the diagnosis can never amount to more than a conjecture. Of simple ulceration, apart from trauma, and of the ulcers consequent on typhoid fever, variola, and pemphigus I have no experience. Some attention has lately been given to the subject of pressure-pouch of the œsophagus, a condition which is apt to be mistaken for the pouching of the œsophagus above the stricture. An excellent description of this condition is given by Mr. Butlin[6] in an article from which it will be seen that it need lead to no confusion with functional stricture. It occurs chiefly in men and is not generally noticed until after forty years of age. There is no real dysphagia, but the one constant symptom is the return of fragments of undigested food, not immediately after being swallowed, but hours and even days afterwards. Pressure on the side of the neck in the posterior triangle, generally on the left side, causes liquids and fragments to return to the mouth. A case illustrating all these conditions was shown by Mr. Cresswell Baber at the last meeting of the Laryngological Society.[7]

Turning finally to the extrinsic causes of œsophageal obstruction which might be confused with functional dysphagia we may have to consider mediastinal new growths, enlarged glands, dislocation backwards of the sternal end of the clavicle, abscess in connexion with Pott's disease, large pericardial effusion (rare), and aneurysm of the aorta. The latter is really the only condition which need detain us, firstly because of its importance, and secondly because of the difficulty it may present in diagnosis. I note that Osler[8] says that dysphagia is a comparatively rare symptom of aneurysm of the thoracic aorta. If this is so it shows the mistaken ideas which might be obtained by limiting oneself to a special department of practice uncontrolled by larger teachings. For the experience gathered from a throat hospital would lead me to the opinion that dysphagia from pressure of an aneurysm is not uncommon. In this view, however, I am supported by the experience of Dr. G. A. Gibson, who states in a recent publication[9] that in aneurysm of the transverse arch of the aorta "interference with swallowing is extremely common," and that when the descending portion of the arch is affected dysphagia is "usually the symptom which calls the attention of the patient to the fact that there is anything wrong." The general symptoms of aneurysm need not here be recapitulated, but brief reference might be made to those cases showing pressure on the œsophagus. To begin with, it should be an inviolable rule to carefully examine every person for aneurysm of the thoracic aorta before forming a diagnosis as to stricture of the œsophagus and before thinking of passing an œsophageal bougie. Sir William Broadbent makes the useful division of aneurysm into aneurysm of symptoms and aneurysm of physical signs. The latter should, if associated with symptoms of pressure on the œsophagus, at once put the practitioner on his guard against passing a bougie for diagnostic purposes. It is in the "aneurysm of symptoms" that great difficulties present themselves. Space prevents me from enlarging on this point, although it requires the most careful consideration, for many are the tales which are related of physicians who have diagnosed a stricture of the œsophagus, either spasmodic or organic, and have passed a solid india-rubber bougie straight into the sac of an aneurysm. Two methods of examination remain to be considered: auscultation of the œsophagus and the use of the œsophageal bougie.

AUSCULTATION OF THE ŒSOPHAGUS.

Stethoscopic examination of the gullet seems to have fallen into some disuse, and it must be confessed that it is a difficult art to acquire and one which is not always reliable in the impressions it conveys. In normal deglutition there may be no sound at all or at most a confused and continuous bubbling. As a rule it is quickly over. When there is organic stricture the most striking symptom is the prolongation of the œsophageal bruit. The test is generally applied with mouthfuls of liquid and the arrest is revealed by a confused and bubbling noise, which gradually diminishes and can be heard descending as the liquid trickles through. In spasmodic functional stricture there is frequently practically no bruit at all if the liquid passes into the œsophagus. If it is rejected there is a loud and sudden bubbling as it is returned.

DANGERS OF THE ŒSOPHAGEAL BOUGIE.

The passing of an œsophageal bougie is sometimes undertaken light-heartedly, as if it were one of the most trivial of diagnostic procedures. For my own part I must confess that I employ it comparatively rarely—it is always the last step in an examination; if there is any suspicion of the presence of an aneurysm or of ulcerated malignant disease it is not passed at all for diagnostic purposes, and I never pass one except in the presence of a third person. These precautions may appear suggestive of timidity, but although those who have had misfortunes with the bougie are doubtless reluctant to publish their experiences there is, I fear, a record of undoubted accidents sufficient to put every practitioner on his guard and to surround the sounding of an œsophagus with the greatest circumspection. One well-known story records that a hollow bougie was passed easily—presumably into the stomach—and a pint or more of milk was poured through it. At the post-mortem examination a few days afterwards the milk was found in the left pleural cavity. The instrument had perforated the floor of a latent form of carcinoma of the gullet. But it is not only that there is danger of a bougie penetrating an aneurysm or the wall of the œsophagus, the simple passage of the instrument into a gullet where it meets with no pathological change is, in itself, not unattended with risk. Gratz is quoted by Lowman as having reported three cases of death from simply passing a stomach tube. Lowman[10] states that he himself knows of a case where a tube was passed into the stomach and the cavity washed out with warm alkaline solution. The patient complained of feeling weak and he was made to lie down, but he continued looking pale; stimulants were given, but he shortly afterwards died. In seeking for an explanation of these unfortunate accidents I have been reminded of the close association between the act of deglutition and the action of the heart. Kronecker has discovered that the act of swallowing seems to remove entirely the inhibitory action of the vagus upon the heart for the time being so that the pulse becomes exceedingly rapid. Dr. Lauder Brunton, who has called attention to this,[11] finds that sipping half a wineglassful of water will raise his own pulse from 76 to considerably over 100. It is, I fancy, possible that in a sensitive subject the passage of a bougie along the œsophagus might remove the inhibitory action of the vagus to a dangerous extent. I readily grant that much can be learned from the passage of a bougie, and as Rolleston remarks in his excellent article in Allbutt's System of Medicine[12] "By means of the bougie, spasm, stricture due to organic cause, and paralysis can be distinguished from each other." All I wish to lay stress on

is the necessity for great caution before deciding to employ the instrument.

SOUNDING THE ŒSOPHAGUS.

A few words as to the passage of the œsophageal bougie. The usual form is that known as Mackenzie's, flattened antero-posteriorly, and, in the words of the advertiser, "I know no better." 13 sizes are made, the measure of each being based on the number of millimetres in the transverse—i.e., their long—diameter. The sizes are reckoned from No. 3 to No. 15. Thus No. 3 measures 3 mm. from side to side, No. 4, 4 mm., and so on through the scale. Nos. 1 and 2 are not made, as they are too small to be of any use. In introducing this the patient should sit in front of a good light with his neck freely uncovered. The upper part of his body and neck is craned forward, while the face is thrown upwards. A moderate sized bougie, from No. 8 to No. 12, is safer to begin with than a sharp-pointed one. It is softened sufficiently by being dipped in warm water. The books always recommend us not to dip it in oil, which is very disagreeable to the patient, but to lubricate it with glycerine. As a matter of practice it has been pointed out by Mr. Hovell that no lubricant whatever is required. It is probable that when any is used it does not pass with the bougie along the gullet—it is mostly deposited in the mouth. The natural secretion of mucus which is sufficient to slide down walnuts, apples, and other hard and angular morsels is quite sufficient to facilitate the passage of the bougie. The instrument should be slightly bent at about an inch from its extremity, so that it will glide easily along the posterior wall of the pharynx. It is then grasped in the operator's right hand about half a foot from its extremity. The left forefinger depresses the tongue so as to reveal the margin of the epiglottis, and at the same time it serves to guide the tip of the instrument behind the larynx. It is then pressed gently but steadily into the gullet. As it passes the cricoid cartilage—especially in cases where the patient spasmodically contracts the upper part of his œsophagus—it is a good plan to make the patient bend his head forwards and at the same time request him to make an attempt to swallow. When he is seen to be doing this the bougie can generally be slipped past the constriction and then, in sailor language, "paid out" into the gullet. This method of "surprising" a stricture is the only one I am conversant with and I think the only one to be recommended. Other methods of "forcing" a stricture appear to me to be too full of risk to be employed. Sometimes the application of cocaine will facilitate the sounding, but it is as well to bear in mind that in neurotic subjects, in whom functional dysphagia is apt to occur, there may be a special predisposition to cocaine intoxication. In many uncomplicated cases some patience, and the trial of different sizes, is required; but if not soon successful, and there is no indication demanding the immediate passage of the instrument, I think that, if the patient shows much nervousness and tendency to spasm, it is wise to defer the examination. Once the patient gets nervous the difficulty of passing the instrument is greatly increased, whereas at a second visit he is more reconciled to the idea, especially if the procedure is approached with confidence. The administration of a general anæsthetic is rarely required.

When the bougie is felt to encounter an impassable obstruction, or when it is grasped in a stricture, it should be seized on a level with the incisor teeth before being withdrawn. It will be remembered that the upper margin of the œsophagus is 6 in. (from 15½ to 17 cm.) distant from the front teeth and that the stomach is reached at a depth of 15½ in. In functional dysphagia the bougie can always be passed. The resistance it meets with is, in my experience, always at the superior constrictor of the œsophagus. Once this is overcome the bougie is felt to be free and easily moveable. In pressure-pouch the bougie will sometimes pass into the pouch and its tip can then be felt on one side of the neck. If two metal bougies are passed, one into the pouch and the other down into the stomach, and a Roentgen photograph be taken, the situation and relation of these two bougies will be seen. Malignant disease occurs with almost equal frequency at either end of the gullet. It may be quite impassable. If a passage is found through it the bougie continues to be grasped by the stricture and is not felt to yield on moving the instrument up and down. Its withdrawal is often accompanied with some blood.

PROGNOSIS.

The prognosis of these cases is good in so far as regards the length of days. As regards their duration, some remain unaltered for years, continuing to nourish themselves sufficiently on fluids. In some the symptoms are intermittent. In many they recur after relief by treatment.

TREATMENT.

The experience of the study or out-patient room might lure us into the conviction that such cases are readily curable, and it is often said in an offhand way that the passage of a bougie is sufficient to cure functional dysphagia. No doubt in a large majority of cases a striking result is speedily brought about. Possibly the laryngologist's *mise en scène* conduces to this rapid result. The darkened room, the glaring bull's-eye lamp, the flashing frontal mirror, and the long, glittering, red bougie which is seen and felt disappearing, apparently by the yard, down the gullet are doubtless all calculated to make an impression on these generally hysterical subjects. If to this procedure strong suggestion is added the patient will generally go straightway and consume a good solid meal with ease. But only too often, and particularly if after-treatment is not followed up, their dysphagia recurs. Some present themselves again and are again relieved; the older cases probably go elsewhere, where they know the bougie is not so readily produced, and a large number refuse to consult anyone and cling to a condition which not unfrequently gives them a local reputation. I have known several cottagers' wives afflicted with this malady—poor women leading a hard life, the hardness of it being increased by the necessity of expending money on milk, eggs, and beef-tea, and who either refuse any treatment or who, having once been relieved by the passage of a bougie, decline to have recourse to it again. Weir-Mitchell writes:[13] "You will be well if you escape this exasperating disorder in your early hysterical cases. It is most enduring and difficult of relief." Personally I have generally found that the mental effect of the passage of the bougie has acted admirably. I have never had recourse to intra-œsophageal electricity and I imagine that it might not be without risk. It is most important to keep up the influence of suggestion. A large number of cases are remarkably anæmic, whether as cause or effect I am unable to say. A long course of hæmatinics is therefore frequently indicated. The further details of treatment do not require particular mention. Our whole armamentarium against hysteria may be called into requisition, and in addition to the nervine tonics we may have to persevere with diet, change, rest, spa treatment, massage, general electricity, &c.

In those cases where a reflex point of irritation is discoverable the treatment is obvious. The irritation must be combated and, if possible, removed. Ovarian or uterine irritation as well as gout and rheumatism may require attention. The cases where the condition is chiefly one of "aphagia" are generally the result of some functional spasm or are associated with it, so that the same treatment is applicable to both forms of functional dysphagia. In the diagnosis of many of these cases we would do well to remember that carcinoma is the most common of all the affections of the œsophagus. In approaching the diagnosis of any case of dysphagia we should have present to our minds the following possibilities in the following order of frequency — cancer, aneurysm, other forms of ulceration (traumatic, syphilitic, and tuberculous), and functional disease. The old advice is very applicable in cases of dysphagia—viz., to hope for the best and prepare for the worst.

Queen Anne-street, W.

[13] Loc. cit.

DEVON AND EXETER HOSPITAL.—At a meeting of the governors of the Devon and Exeter Hospital held on Nov. 24th the financial position of the institution came under discussion. One of the governors stated that when it was decided to erect the present new buildings the expenditure was estimated at about £12,000 and a contract was entered into for that amount. He added that at present they had spent £25,000, they owed a further sum not yet ascertained, and they had used all the money given and specially subscribed; they had further sold out stock which brought in £800 per annum towards the maintenance of the hospital. In conclusion he moved that the further work, for which a tender of £4500 had been accepted, be not proceeded with and that a sum not exceeding £700 be expended upon necessary improvements. The motion was eventually carried by 27 votes to 2.

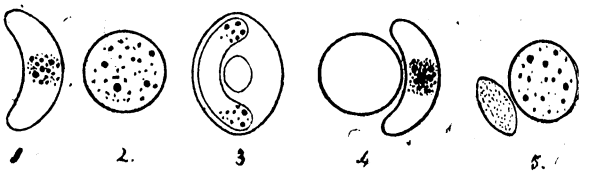
THE MOSQUITO AND THE MALARIA "PARASITE."

BY E. LAWRIE, M.B. EDIN.,
LIEUTENANT-COLONEL I.M.S.; RESIDENCY SURGEON, HYDERABAD, DECCAN.



IN THE LANCET of Nov. 13th, 1897, Dr. MacCallum of the Johns Hopkins University published an account of a "sexual process" in halteridium, a body which is stated by Dr. Patrick Manson to be "an intra-corpuscular parasite of birds closely allied to the malaria parasite in man." In THE LANCET of Feb. 12th following it was pointed out that Dr. MacCallum's description appeared to be modelled after the account of the fertilisation of the ovum by von Beneden, in the section on Embryology by Professor Schäfer, in Quain's Anatomy. No explanation has been offered of the similitude between the two accounts. The subject is one of such vast importance that the leading facts of both descriptions are reproduced here:—

VON BENEDEN. *The fertilisation of the ovum.*	MACCALLUM. *The fertilisation of the Laveran body.*
1. The spermatozoon embeds itself in the ovum.	1. One flagellum plunges its head and wriggles its whole body into the female sphere.
2. The ovum becomes slightly protruded at the point of contact.	2. A conical process appears at one side of the female organism.
3. One spermatozoon only embeds itself in the ovum.	3. One flagellum only embeds itself in the female sphere.
4. As the spermatozoon passes towards the centre of the ovum it exerts a peculiar action upon the granules.	4. As the flagellum passes into the centre of the female sphere the "granules are churned up."

The offspring of Dr. MacCallum's fancied "sexual process," which was warmly welcomed and heralded by the zealous Professor Osler, was depicted by him as an organism of spindle shape with a hyaline beak, which "*may be* the resistant form which escapes from the body during life into the external world." The words "may be" were italicised in order to call attention to "the ingenious way the plasmodists have of throwing out a hint or suggestion which is afterwards quoted by themselves as an approved scientific fact." Events have demonstrated the entire reasonableness of this *caveat*. Dr. Patrick Manson has recently quoted Dr. MacCallum's version as an approved scientific fact and Major Ronald Ross has made it the sole basis of his romantic verification of Dr. Manson's hypothesis that the mosquito is the liberating agent of malaria as well as filaria. It is obvious that if Dr. MacCallum's account of the fertilisation of the Laveran body is not founded upon fact the whole of the mosquito theory of malaria falls to the ground.

The facts with regard to the Laveran body in the blood in malaria and its *alter ego* in the blood of healthy birds are as follows. In malarious fever in man when the spleen is not very much diseased cells are found in the blood, either intra- or extra-corpuscular, which contain dark granules similar to the granules of the leucocyte. These cells are called after their discoverer Laveran bodies or plasmodia. *They are not found in all cases of malarious fever.* Therefore they cannot be the cause of the disease. When the granules in the Laveran body are scattered throughout its protoplasms its shape is spherical; when they are collected in the centre of the cell it becomes spindle-shaped and semilunar and it is known as the malarial crescent. In drawn blood, if the relative density of the fluid in the cells and that in which they lie is altered, as, for example, by the addition of water, the crescent becomes spherical, the granules dance about with the boiling-water movement of Laveran, and processes of protoplasm are occasionally thrown out which are called flagella. On the other hand, in certain birds which are apparently in perfect health—pigeons, crows, and sparrows, for instance—cells are found in the blood, either intra- or extra-corpuscular, which contain dark granules similar to the granules of the leucocyte. These cells are called by the plasmodists *halter*-idia or proteosoma, according as they are semilunar or spherical in shape. When these cells are intra-corpuscular they are at first spherical. Afterwards they become semilunar because their shape is determined by the nucleus of the red blood corpuscle in which they grow. When they grow still larger they push the nucleus aside and eventually burst out of the corpuscle, and after they become free if the density of the fluid in which they lie is altered, as, for example, by the addition of water, they become spherical, if they are not so already, the granules exhibit the true boiling water movement of Laveran, and flagella are occasionally thrown out.

The so-called halteridia and proteosoma are identical with the Laveran bodies in every respect except one. The one difference between them is that in the malaria crescent the granules are collected in the centre of the cell, whereas in the halteridium and in the early stages of proteosoma they are found principally towards the ends. The following diagram shows the points of resemblance between the Laveran bodies in malarial blood and the halteridium of proteosoma in the blood of apparently healthy birds.

1. The malaria crescent.
2. The spherical form assumed indifferently by 1 when water is added to the blood and by 3 when it escapes from the red blood cell.
3. The "halteridium" in the oval-shaped nucleated red-blood corpuscle of birds, showing how it is compelled by the position of the nucleus to take the semilunar form.
4. The malaria crescent as it is frequently seen in contact with a red-blood corpuscle, showing how it may be compelled by pressure against the round blood cell to take the semilunar shape.
5. The "halteridium" free, having attached to it, as it almost invariably has, the nucleus of the red-blood corpuscle in which it grew.

The semilunar shape of the Laveran body, whether intra- or extra-corpuscular, must be regarded as due to mechanical causes and adventitious; and whether these bodies—the plasmodium, halteridium, or proteosoma—are met with in the blood or man or of birds they are one and the same thing, and to save confusion and misleading error they should all be called by the one name of Laveran bodies.

The following facts have been established by an examination of the blood of birds in the laboratory of the Hyderabad Medical School. 1. Laveran bodies are found in the blood of apparently healthy birds. 2. They are not found in the blood of birds before they are fledged and leave the nest. This was pointed out originally by Captain Johnston, I.M.S. 3. They are not met with in the blood of all birds. In 101 sparrows examined they were found in the blood in 81 per cent.; in 36 crows in 70 per cent.; in 38 pigeons they were found in every one of 32 adult birds; none were found in the blood of any unfledged birds or in that of 10 ducks, 12 fowls, and 4 hawks. 4. The Laveran bodies in birds, like those found in malarial blood, cannot be cultivated in pure media outside the blood. 5. The Laveran bodies cannot be propagated or reproduced by inoculation. 6. Two young unfledged pigeons were brought up by hand in the laboratory. Neither had Laveran bodies in the blood. One was fed on grain and filtered water; the other on grain, on the spleen of a crow and the blood of a pigeon with halteridium, and water taken from malarious swamps. The one fed on filtered water developed Laveran bodies in the blood on the twentieth day;[1] the one fed on swamp water and halteridia has not yet developed them. 7. The temperature of the birds, and the size and weight of their spleen, bear no relation to the Laveran bodies found in the blood. 8. No such phenomena as "*ex*-flagellation" or a "sexual process" was ever observed among the Laveran bodies. Flagella sometimes separate from the cell from which they are thrown out originally as processes of protoplasm, but this only takes place in drawn blood as part of the process of their ultimate disappearance.

We are now in a position to form a correct opinion as to the accuracy of the Ross-Manson hypothesis of the mosquito and malaria. Before considering it there are one or two points which demand some explanation. In the first place the average length of an ordinary mosquito's body in this part of the world is about 3 mm. In the diagram of the insect's empty stomach given with Dr. Manson's paper in the *British Medical*

[1] The young pigeon fed upon swamp water is since dead. We tried to colour the blood corpuscles during life by subcutaneous injections of methylene blue, but it died after the second injection. On post-mortem examination the heart was found to be coloured bright blue; very few of the blood cells had taken the stain.

Digitized by Google

Journal the length of this organ, together with the cut ends of the œsophagus (*sic*) and intestine, is 2·5 mm. according to the scale appended to the diagram by Major Ross. In the second place Major Ross refers repeatedly to feeding mosquitoes on the blood of sparrows and larks. It would be interesting to know if these birds were plucked beforehand as it is almost an impossibility for a mosquito to sting a bird and suck its blood as long as the feathers are intact. In the third place Dr. Manson and Major Ross write of the dissection of a mosquito as if it were child's play; "hecatombs of mosquitos" were treated in this way "in the cause of science"—245 in one batch and 249 in another. This is far too easy. Let any one who is inclined to regard the dissection of a mosquito as an easy matter try it and he will find that even with a very high-power dissecting microscope it is impracticable to display the insect's stomach in such a manner as to be able to count "pigmented cells" on its wall.

The story as told by Dr. Patrick Manson of Major Ronald Ross's discoveries with regard to the mosquito and malaria may now be briefly referred to. About a year ago Major Ronald Ross discovered a cell containing pigment in the stomach of a "dapple-winged" mosquito, and the optical characters of this pigment "were such that it seemed to be in every way identical with the pigment which is so characteristic of the malarial parasite." It has never been proved yet that there is any connexion whatever between malarious fever and "pigment," and it is not pretended that there was anything but "pigment" to identify this pigmented cell of Major Ross's with malaria, but on these slender grounds Major Ross "was sure that he had now discovered the extra-corporeal form of the malarial parasite. Here, however, fact and theory seemed to diverge. Fortunately at this juncture help came from America." The help from America consisted of Dr. MacCallum's "sexual process," the results of which are described and improved upon by Dr. Manson in graphic terms: "After a time the impregnated spheres changed shape and acquired locomotive powers—became, in fact, *travelling vermicules* containing the entire substance of the original halteridium, including its pigment. They exhibited great powers of penetration. Depend upon it this locomotive penetrating power has a purpose."

It is a pity that before putting forward a controvertible theory as an approved scientific fact Dr. Manson and Major Ross did not take steps as they were bound to do to confirm Dr. MacCallum's observations on the locomotive penetrating animal with the hyaline beak. This would have been a simple matter if Dr. McCallum's animals actually existed in the blood, but it was not done, and the story, which Dr. Manson truly says is "a really marvellous story," may be continued for what it is worth from this point by Major Ross. Having opportunely discovered the "pigmented body" in the dissected stomachs of mosquitoes fed on the blood of malarious sparrows Major Ross asserts that because Dr. MacCallum's halteridium organism with the hyaline beak possesses locomotive penetrating power which enables it to "pass indifferently," according to Dr. MacCallum and Dr. Manson, "through red blood corpuscles and white blood corpuscles," therefore his "pigmented body," which is the unattested offspring of proteosoma, must also possess the power of penetration and consequently of passing indifferently through the wall of the mosquito's stomach. This is, of course, a *non sequitur*, nevertheless it is a fair specimen of plasmodial logic. When once the proteosoma organisms have penetrated as far as the outside of the mosquito's stomach it is an easy task to call them "proteosoma coccidia" and to trace their progeny in the form of Major Ross's "germinal rods"—first cousins apparently of Dr. Manson's "travelling vermicules"—through the "well-known white blood of the mosquito," into its poison gland, out again through its proboscis, and so back into the circulation of man and birds. Thus happily is the *rôle* of the mosquito in malaria completed by Major Ross on the lines conjectured by Dr. Manson. Henceforth in order to free the world of malaria it is only necessary to free it of mosquitoes. The *British Medical Journal* recommends the Government of India to do this by "the application of kerosene once a month to the surface of their breeding pools."

This, then, is the outcome of malarial parasitology, a crusade against the mosquito. Although not one single theory of fever based upon this "science" is founded on a proved fact, and notwithstanding that it is known that pools constitute one only of the many places in which the mosquito breeds, all the water in India is forthwith to be polluted once a month with kerosene. That a crusade against mosquitoes should be gravely proposed by a very influential section of the medical press is strong evidence of the profound disorganisation of professional opinion which has resulted from the speculations and conjectures of the plasmodists. Fortunately, certain facts are known about malaria which no hypothesis and no amount of sophistry or untruth can alter. 1. The commonest form of malarious fever is the quotidian, in which there is an attack every day, 1, 1, 1, 1, 1. 2. The tertian form of ague is less common, in which there is an attack every alternate day, 1 –, 1 –, 1 –, 1 –, 1 –, 1 –. 3. Quartan ague, in which there is an attack every fourth day, is comparatively rare. 1 – –, 1 – –, 1 – –, 1 – –, 1. 4. In irregular ague the fever is of a remittent rather than of an intermittent type. 5. Quinine prevents and also cures malarious fever. 6. Malarious fever can as a rule be readily and with certainty diagnosed by the history of the case, by the clinical thermometer, and by the condition of the spleen.

These are solid facts which have long been well known to every observant practitioner in malarious localities. It is only necessary to add that it is not possible to diagnose malarious fever, either the fever itself or its type, with any certainty at all by means of the microscope. One case only need be cited by way of illustration. Not long ago a patient was sent to me from the country to be operated upon for an abdominal tumour supposed to be ovarian. I diagnosed the tumour to be a displaced malarious spleen and she had fever every day. If the microscope were reliable in the diagnosis of malaria the point could have been decided in a few minutes, but on microscopic examination there were no Laveran bodies in the blood. The diagnosis had therefore to be settled by quinine, under the influence of which the tumour slowly disappeared. To meet the speculations and conjectures of the plasmodists no less than the requirements of malaria "parasite" an attempt has been made to overthrow the nomenclature of malarious disease. Quotidian ague has to be proscribed because of the difficulty the plasmodists experience of adapting the otherwise plausible and fascinating life-cycle of the "parasite" to a single day. The most credulous individual can hardly be expected to believe that the quotidian "parasite" can in one day as a mere spore chase and capture a red corpuscle in the circulating blood, get into its interior, grow up and devour its hæmoglobin, digest it and develop "pigment," and then sporulate and give birth to from 10 to 12 young ones. But there is not the same difficulty about swallowing a forty-eight hours' cycle, therefore the majority of "parasites" in future are to be tertians. If anything were wanting to complete the confusion in the profession which has been brought about by the grotesque science of malarial parasitology it is furnished by the amusing, if hurried, African tour of Professor Koch. Koch has announced that there is no such condition as quotidian ague; that he has discovered a new form of tertian ague in which the intermissions occur every

1 2 3 4,1 2 3 4,1 2 3 4,1 2 3 4.

fourth day —, 1 1 —, 1 1 —, 1 1 —, 1 1 —; that the most pernicious form of African fever is nothing but cinchonism; and that the presence of the malaria crescent in the blood is a sign of immunity.

There has been too much unscientific speculation and conjecture with regard to malarious fever, and what is now required is a commission to inquire into the true physiology of the blood-cells, of which very little is known and without which the pathology of malaria will remain a sealed book. Until the physiology of the healthy blood corpuscles is thoroughly worked out speculation regarding the Laveran bodies is necessarily idle. The Laveran bodies are to be looked upon as perverted modifications of the natural cells in the blood, in which they occur as mere "sports," so to speak, of the natural blood corpuscles, and in no way as new or independent formations. The essence of this belief is that the Laveran bodies are products of the blood and are the progeny of the cells already existing there, their physical peculiarities being entirely due to the altered cell formation of natural structures. Formation in a word outstrips organisation, and the offspring of the blood corpuscles—the "sports" or Laveran bodies—fail to arrive at precise resemblance to the parents from which they take their birth.[2]

[2] This passage is taken, *mutatis mutandis*, from the *Times* leading article on Virchow of Oct. 6th, 1898.

NOTES ON A CASE OF BLACKWATER FEVER.

BY F. PERCIVAL MACKIE, L.R.C.P. LOND., M.R.C.S. ENG.,

JUNIOR ASSISTANT MEDICAL OFFICER, COUNTY ASYLUM, SHREWSBURY; LATE ASSISTANT HOUSE PHYSICIAN AT THE BRISTOL GENERAL HOSPITAL.

I MUST express my indebtedness to Dr. Theodore Fisher, of Clifton, for permission to publish the case and also for clinical notes supplied.

The patient was a missionary who had recently returned from Africa. He described an attack of "hæmoglobinuric fever" from which he suffered in September, 1894, when at Benguella on the west coast. That was his first attack. After returning from a cycle ride from Bath to Bristol against a strong wind he was taken ill with vomiting and fever running up to 102·6° F., but without an initial rigor. The next day at 2 A.M., however, he had a severe rigor lasting twenty minutes in which the temperature went up to 103°. On the third day a second rigor occurred, the temperature going up to the same height as before. He continued to vomit at intervals and his condition was considered to be very serious. That evening his urine was noticed to be black, like porter, and his temperature was then 102·6°. On the fourth day the vomiting ceased, the rigors also left him, and the temperature went down to 99°, where it remained for several days. The dense, porter-like colour of the urine remained for fifty hours from its first appearance before any change became evident, when it began gradually to clear up.

Examination of the blood was made twenty-four hours after the last rigor. The count showed the presence of 4,000,000 red cells and 6200 colourless corpuscles per cubic millimetre. The white corpuscles were in the following proportion: polymorphonuclear, 75 per cent.; lymphocytes, 18 per cent.; large mononuclear, 4 per cent.; and coarsely granular eosinophile, 3 per cent. The examination of the fresh specimen of blood showed absence of rouleaux formation; there was very little distortion of blood-cells either in shape or size, and no organisms were visible. In specimens of blood fixed in Gulland's solution and counter-stained with methylene blue the following changes were noticed. The most obvious point was the presence of a considerable number of faded or phantom-like red cells which looked as if they had had the colour washed out of them and presented only a thin pink rim and centre, whilst the more normal cells around them were deeply stained with eosine. These corpuscles were not distorted or in any way broken up, neither did they contain any malarial organisms. In the examination of 6 or 8 films of blood about 8 definite intra-corpusclar malarial organisms were seen, all of a spherical shape and containing a dot of black pigment. All of them were small, none of them nearly filling up the cell they inhabited. In one place a rosette-shaped organism had evidently just broken up, as there was a collection of 8 or 10 spore-like bodies loosely arranged around a small mass of pigment. There were a considerable number of faintly stained extra-corpuscular bodies, mostly in groups of 2 or 3 from which could be traced delicate flagella. The blood which had been collected in the pipette of a Thoma Zeiss hæmocytometer was re-examined after two days and there was a great increase apparent in the extra-corpuscular variety, as numbers of actively motile organisms were seen hurrying about the field. These when examined with an oil immersion lens were seen to be spherical and not bacilli, although owing to the free dilution of the blood with saline solution at the time of its withdrawal satisfactory permanent preparations could not be obtained.

Examination of the urine was unfortunately not carried out until it had almost regained its normal colour. Spectroscopic examination revealed a faint hæmaglobin band. The reaction was acid. The specific gravity was 1015. There was no albumin or reducing substance. There was a dirty-brown sediment. Microscopical examination showed the presence of some reddish-brown granular tube-casts and also numbers of small rounded cells resembling the bladder epithelium cells and containing some refractile spherical bodies. There were no blood corpuscles. Scattered about the field were seen small clusters of oval transparent bodies collected in groups of about 4 or 6, and sometimes smaller individuals were seen radiating from the central group. They stained easily and deeply with methylene blue and were seen to be growing by gemmation. The urine, which had been kept in a stoppered bottle, was examined at the end of a few days and the number of these bodies was found to have considerably increased. Some of the sediment was added to a solution of glucose in water and put in a warm place. When examined at the end of forty-eight hours the fluid was turbid and there were considerable numbers of these torulæ, but there was no decrease in the specific gravity of the liquid nor was there any gas formation. Thus, although they seemed to be some kind of torula, yet it was evidently not the common yeast plant. Some such bodies as these have several times been noticed by other observers in the urine of patients suffering from hæmoglobinuric fever, but their origin and significance are quite unknown.

Shrewsbury.

AN OUTBREAK OF ACUTE DERMATITIS DUE TO ZINC SALT AND ASSOCIATED WITH CLOTHING.

BY GODFREY TAUNTON, M.R.C.S. ENG., L.R.C.P. LOND.,

ASSISTANT HOUSE PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM.

ON Nov. 23rd, 1898, a man came to the out-patient department of the General Hospital, Birmingham, complaining of a rash on the front of his right wrist which presented the appearance of a patch of urticaria. It was associated with itching, was apparently present on no other part of the body, and there was nothing to distinguish it from ordinary urticaria. The patient ascribed the condition to a new blue frieze overcoat which he had only put on that morning, and he mentioned that several of his fellow workmen who had also been provided with similar new overcoats that morning were suffering from the same complaint. He was immediately succeeded by another man in the same employ who exhibited a rash, also in the region of the wrists and corresponding to the margins of the sleeves. This case presented a somewhat different appearance from the former, and appeared to be a more advanced stage of the same condition. On one of the second patient's wrists was a patch about 1½ in. by ½ in. of numerous minute cream-white spots, and in the middle of each of these there was a hair follicle which stood out as a dark centre. The margin of the patch was outlined by a narrow zone of hyperæmia. This patient complained of a pricking rather than an itching sensation. The second man was followed by others who presented the same appearances on one or both wrists or on the neck. In one of the cases a patch was present on the back of the calf of the right leg, corresponding to the level of the lower margin of his overcoat. For some reason he had omitted to put on his leggings that morning, and as the day was wet the moisture from his coat had soaked through his trousers. Towards the evening other men similarly affected arrived, their cases exhibiting a still later stage in the condition. There were now patches averaging from ⅛ in. to ¼ in. They were of a uniform cream-white colour, evidently resulting from the spreading and fusion of the individual minute white spots which I have already mentioned. The patches were slightly depressed and the appearance was now strongly suggestive of necrosis of the epidermis following the application of a strong irritant. On the margins of some of the necrosed patches was an inflammatory zone, while in places the minute white spots were to be seen as before. Tactile sensation at this stage was impaired but not lost. Some of the patches had a somewhat bluish tint, probably due to the dye of the coat. Altogether 21 patients were seen on Nov. 23rd. On the next day (Nov. 24th) the old cases appeared for inspection, in addition to which there were 13 new cases. The old cases more or less presented the same appearance as on the previous evening, but tactile sensation was now entirely lost in the necrosed areas. It was noticed that the appearances were most marked in the neighbourhood of existing abrasions. In 3 cases there was some spreading inflammation up the arm with enlarged glands in the axilla.

There seems no doubt that the cause of the condition described was to be found in some irritating substance contained in the new overcoats. The day being wet the moisture absorbed some of this deleterious material and so

Digitized by Google

brought it into contact with the skin at the most exposed parts, especially at the wrists. The association of the condition with moisture is confirmed by the fact that one or two boys in the same employment received their overcoats about a fortnight earlier but only exhibited symptoms on the same day as the others, Nov. 23rd being the first really wet day since that time. An infusion of the cloth was made. It had an acid reaction and a sweet astringent taste and on analysis it was found to contain zinc chloride.

Birmingham.

DIPHTHERIA BACILLI IN URINE.

BY H. W. L. BARLOW, M.B. OXON., M.R.C.S. ENG., D.P.H.

IN view of the observations of Captain F. Smith, R.A.M.C., on diphtheria bacilli in the urine of guinea-pigs[1] the following case may be of interest.

The patient, a well-nourished single woman, aged nineteen years, was admitted to Brighton Isolation Hospital on Jan. 8th, 1898, with patches of yellowish membranous exudate containing Klebs-Löffler bacilli on both tonsils, together with moderate pyrexia, a relatively slow but high-tension pulse, and smoky urine. All else was normal: there were no signs of cardiac hypertrophy, there had never been any œdema, and there were no retinal hæmorrhages. She had had small-pox in infancy and influenza a year or two ago, but no other illness except occasional attacks of headache and vomiting. Dark-coloured urine was first noticed on the morning of admission—i.e., the third day. It was acid, it contained both albumin and blood, and it showed urates, casts, and bacilli, some of the latter resembling those of diphtheria. Serum cultures plated out on agar showed on the third, fourth, eighth, twelfth, thirteenth, sixteenth, and twenty-first days of the disease a diphtheria-like organism besides some other forms. This bacillus disappeared as the nephritis wore off (no bacilli and very little albumin were found on the fifteenth day) and reappeared for a short time with a relapse on the sixteenth day, ultimately disappearing altogether. In one doubtful instance only did cultures from other urines in the ward show an organism at all similar to this. A pure culture obtained by plate cultivation was compared step by step with similar cultures of the same age of long Klebs-Löffler bacilli from a fatal case, of Hoffmann's pseudo-diphtheria bacillus, and of a doubtful form isolated from the throat from another case. The last-named proved quite distinct and need not be further considered. The points of difference between the organism from urine and the Klebs-Löffler bacillus did not amount to more than are usually present between the three or four different types of diphtheria bacilli in throat swabs. These bacilli were just as characteristically irregular in form, but they were shorter and apparently of more rapid growth. Their distinguishing features were, first, no growth on gelatin at room temperature; secondly, alkaline glucose broth acidified within twenty-four hours; thirdly, each bacillus showed three or four granules apiece when stained with methylene blue and bismarck brown; and, fourthly, both colonies and streak cultures only differed from those of Klebs-Löffler in minor details. Owing to an accident their pathogenicity to guinea-pigs was not tested. A remarkable point is that cultures could be obtained from the acid urinary sediment after standing for eight days at the room temperature; but this does not, as was first thought, militate against the organisms being diphtheritic, for Klebs-Löffler bacilli not only live but multiply in faintly acid peptone broth containing urea if kept at 37° C. The bacilli in the throat swab were both long and short, the latter being most persistent. The urine always reacted acid to litmus to a degree not determined.

[1] THE LANCET, Nov. 19th, 1898.

Some kind of micro-organism might nearly always be found in urine and it would not be supposed to have reached it through the kidney unless all other paths were closed. Though cleanliness was ensured it was manifestly impossible in this case to take all the precautions which Captain Smith adopted and it must remain to that extent inconclusive. The presence of other forms shows that contamination did occur, but they were variable and the diphtheria constant and if not explained by a kidney infection the casual co-existence of nephritis and bacilli on seven or eight occasions throughout a fortnight or more would remain a rather curious coincidence.

Diphtheritic nephritis, always rare, is decreasing year by year in the metropolitan hospitals. During the last three years it occurred in only 0·77 per cent. of over 13,000 cases and, taking 1897 alone, the percentage is less than half this—namely, 0·34 per cent.—while that of albuminuria remains about 45 per cent. Bacilli have been found post mortem in the kidney by Kanthack and others, but they do not seem to be always associated with nephritis, and if found in other cases their presence is evidently exceptional.

Urmston.

THE TREATMENT OF WHOOPING-COUGH

BY G. ARBOUR STEPHENS, M.D., B.SC. LOND.

I HAVE lately been investigating the subject of whooping-cough, by which I mean the very infectious disease characterised by a convulsive cough terminating in the readily recognised "whoop." In this investigation I have been considerably assisted by the fact that Mr. Hubert Thomas placed a large number of the cases of this complaint which existed extensively in his district at my disposal. My attention was particularly drawn to the subject by a small experiment upon myself. When I had an attack of pharyngitis I found that by tickling the external auditory meatus or the tympanum I produced a cough with the characteristic "whoop." This led me to inquire into the state of the patients' ears in cases of whooping-cough and in nearly every case I found that they either had pain in their ears, as evidenced by the fact that they resented their mothers' washing or even touching those organs, or else that there existed a semi-fluid discharge which in some cases had been present for some time. Having found such a persistent sign or symptom I decided to find out whether treatment applied locally might ease the pain or diminish the discharge and by so doing modify or terminate the course of the disease

The course of treatment I decided on was as follows. I syringed out the ears night and morning with lukewarm boric lotion or water and applied to the meatus and tympanum a paint consisting of 23 gr. of hydrochlorate of cocaine, 4 drachms of glycerine, 20 minims of solution of perchloride of mercury, and water to 1 ounce. The result of this treatment was that in every case the patient was benefited and the whooping-cough was got rid of. In many cases, in addition to what I consider the essential symptoms of whooping-cough, there were present bronchitis, pharyngitis, or laryngitis. These, I need hardly say, did not yield to the treatment above described, and in some cases they persisted for several days after the "whoop" had disappeared. As has been often noticed by other observers the whooping-cough followed in the wake of measles, and in those cases which did succeed measles there was nearly always found a discharge which had continued from the prior attack of measles. In the first few cases I had some trouble in introducing such a novel form of treatment as a substitute for the more othodox bottle of medicine, but having got the first few patients better their friends and relations paved the way for the others. The following are a few of the cases:—

CASE 1.—A boy, aged four years, had had cough for two or three weeks and a discharge from the ears for eleven months. With the cough there was vomiting. The mother "could not touch the ears" owing to the pain. The ears were syringed and painted. The child slept better the same night and "whooped" much less the next day, when the ears were again syringed and painted. On the third day the child was not very bright and the tongue was furred, but the "whoop" continued to improve and the patient had had a very good night. I ordered a dose of mercury with chalk. The child was decidedly better on the fourth day, having

Digitized by Google

only "whooped" once in the twenty-four hours, and on the fifth day he was out playing and quite free from "whoop."

CASE 2.—A girl, aged seventeen months, had had cough with "whoop" for a week and, as in Case 1, there was vomiting with the cough. For six months there had been discharge from the ears. The child frequently put her hands up to her ears. There was some bronchitis. Both ears were syringed and painted. On the second day I found the child very peevish and irritable and she was evidently no better. I again syringed and painted the ears. The next day the child was much less peevish and altogether much better. She hardly "whooped" at all, but there was still some bronchitis. On the fourth day she had, it appeared, only "whooped" once in the twenty-four hours and she took food better. The child was practically well on the fifth day, except for an occasional cough, which was, however, unaccompanied by "whoop."

CASE 3.—A girl, aged four years, had had cough with "whoop" and vomiting for from two to three weeks, and the ears had been discharging for six months, "ever since," it was said, "she had had measles." I only syringed the ears but did not paint them. The child was no better on the second day. She had had a bad night. I syringed and painted the ears and she had a much better night and slept well, being only troubled once during the night with a bout of "whooping" cough. On the third day she was much better. She was still better on the fourth day, having hardly "whooped" at all for twenty-four hours, but she "whooped" once or twice in the evening. Syringing, however, stopped it and she slept well. On the sixth day the child was quite well.

CASE 4.—A girl, aged four and a half years, had had cough with "whoop" for two weeks. Her mother had been unable to wash her ears for four weeks. She had had bad nights and her cough was accompanied with vomiting. Her face was puffed with coughing, there was an ulcer under the tongue and a semi-fluid discharge from the ears which I syringed and painted at 6 P.M. The patient slept well till 10 P.M. but had a restless night, though she "whooped" less than on the previous night. On the third day the child, as reported to me, "had not got so phlegmy a cough." She had slept much better on the previous night and had only "whooped" twice between 11 A.M. and 7 P.M. She had not vomited since the first painting. The child was much better on the fourth day. She had had such a good night that the mother was able to sleep throughout the night, an experience she had not had for a fortnight. The child was so well on the fifth day that the mother told me that "the neighbours were asking what medicine she had had."

CASE 5.—A boy, aged two and a half years, a brother of the little girl mentioned in Case 4, had a nasty cough with vomiting but no "whoop." The remark made to me was that the child "looked exactly as if he were going to have whooping-cough." I syringed and painted the ears. The boy slept well and the next day I found that there had been no vomiting since. The patient had quite lost the cough on the third day and developed no "whoop."

CASE 6.—A girl, aged four years, had been suffering from whooping-cough for sixteen days and had had very bad nights. There was discharge from both ears and I painted and syringed them. I saw the patient four days after. She was no better, though the first night after painting she slept very well. I again painted and syringed the ears and the next day the child was much better, the "whoop" being considerably less. The child was practically well on the sixth day, so much so that the mother ceased to bring her to me.

CASE 7.—A girl, aged two years, a sister of the patient in Case 6, had had whooping-cough for fourteen days, with very bad nights. She coughed till she, in the mother's words, "got black in the face." There was discharge from both ears, which I syringed and painted. The child had a good night and on the next day took food much better. She hardly whooped at all on the following day and she became quite well on the fourth day.

CASE 8.—An infant, aged three months, had had whooping-cough for three weeks. As in the previous case it was said that "she got black in the face." Both ears were discharging and I was told that she had had "two fits." The ears were syringed and painted. The child had a better night and "whooped" less the next day and took the breast better. She again had a good night, having only "whooped" once and she has not "whooped" since.

I have given these 8 cases as typical of a cough which after being under treatment for a few days entirely lost the bouts of "whooping," though in some cases bronchitis lasted for several days. I could add many other cases to show both the ear symptoms and the effect of local treatment but do not think it necessary. As an explanation of the pathology of these cases I consider that there is a small local inflammation in the meatus starting independently of or succeeding to an attack of measles, and that this inflammation irritates the nerve filaments which are connected with the root ganglion of the vagus and so stimulates the vagus itself in some or all of its branches. The laryngeal branches will account not only for the spasm but also for the "whoop" by producing a temporary trophic lesion of the laryngeal mucous membrane against which the cold air, which is invariably drawn in through the mouth, strikes. I also think a similar trophic lesion of a temporary nature occurs in the stomach and lungs by a passing irritation of the vagus branches which results in the secretion of a large amount of mucus.

I have made an attempt to cultivate some bacteria from the ear, but so far I have not succeeded. There is one difficulty in the way of such cultivation, and that is that in a large number of the cases the patients are dirty and live in dirty houses. However, whether the cultivation be successful or not, I trust that I have shown that by syringing and painting the ears a great improvement can be produced, which is, after all, of greater consequence to the little patients than the cultivation of any amount of germs.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF CYST OF THE GREAT OMENTUM REMOVED BY OPERATION.

BY JAMES BRAITHWAITE, M.D. LOND.,
OBSTETRIC PHYSICIAN AND SURGEON TO THE LEEDS GENERAL INFIRMARY; EDITOR OF THE "RETROSPECT OF MEDICINE," ETC.

A FEMALE child, aged four years, was brought to me in December, 1897, in consequence of the abdomen being swollen. The abdomen clearly contained a large amount of fluid which, as it lay in front of the bowels, presumably was encysted. The whole of the front of the abdomen was dull on percussion except for about 3 in. below the ensiform cartilage. Both loins were resonant. The least touch caused a fluid wave from side to side. Presumably, therefore, the fluid was thin in consistence and the cyst, whatever it might be, was probably unilocular. The body measured 1 ft. 10½ in. round at the level of the umbilicus, and this increased 1 in. during the next two months. Otherwise the child appeared to be in good health and was described by its parents as "very energetic." I recommended operation and this was done on March 10th last. Mr. Appleyard o Bradford gave ether and Dr. Lawson of Hebden Bridge and Dr. Oldfield of Leeds assisted me. The cyst was found to be entirely in the great omentum and was, except for an adhesion to the intestine, removed without any difficulty. It contained three and a half pints of fluid which was clear and watery. Necessarily a certain amount of the omentum was removed with the cyst. When opened the fresh cyst showed on its inner surface a number of iridescent patches almost like mother-of-pearl. These, however, now show much less distinctly, as it has been kept in spirit eight months. The child recovered rapidly and satisfactorily except that there was a small stitch abscess at one spot.

The extreme rarity of omental cysts seems to render this case worth publishing. I have not been able to find records of more than six such cases. The most interesting is one related by Mr. Alban Doran for Dr. Bantock in the Transactions of the Obstetrical Society of London, 1881. This was a cyst of considerable size, and the case was precisely parallel to the one I have related except that it occurred in an elderly woman. There is a case of what is called "a remarkable cyst in the omentum" related by Dr. Gairdner in the Transactions of the Pathological Society of

Digitized by Google

London, 1851–52. The only German case which I can find is one by Schwartzenberger, published in 1894. He styles it "a multilocular lympho cyst of the omentum." Besides these there are 2 other cases, 1 in the *Medical Times and Gazette* in 1862 and the other in the *Medical Press and Circular* in 1883. Mr. Alban Doran mentions, too, that there is a small omental cyst without any clinical history contained in the Museum of the Royal College of Surgeons of England.

The cyst belonging to the case which I have related, when empty and collapsed, is about as big as a large cocoanut and its walls are tough and strong. When distended with fluid at the time of the operation the walls were thin and of the bluish colour seen in an ordinary ovarian cyst. It is impossible from an examination of this cyst to say in what structure it had its origin. It is now in the Museum of the Medical Department of the Yorkshire College.

Leeds.

A NEW METHOD IN SHOULDER PRESENTATIONS.

BY A. J. TURNER, M.D. DURH.

IF there is one form of presentation in midwifery practice which a busy practitioner dislikes more than another to encounter I suppose it is the shoulder, especially if well advanced before it comes under his notice. I have therefore been prevailed upon to describe a method which I have made use of for the last ten years, for though happily these cases are comparatively rare it has been of great practical value in five.

In the first stage, the arm of the fœtus being protruded, it is doubled at the elbow, the fingers resting on the shoulder, forming as it were the point of a wedge which is now pushed back again into the uterus, in the interval of the pains, the upward movement being continued by the operator's bent forefinger pressed against the shoulder. In the second stage the accoucheur's middle finger is extended and by preference placed in the mouth of the fœtus or on some firm bony point of the head. Now, with the assistance of the operator's other hand external to the mother's abdomen, the head is drawn into a better position, where, should the pains still be strong, it may be left to nature, or the instruments applied if considered advisable.

This method saves all efforts at podalic version, over-distension of the uterus by the addition of the hand (only two fingers actually entering the uterus), as well as decapitation, &c. It may be made use of after the arm has been protruded for some time and takes but a few minutes to perform.

The cases alluded to had been in hand for from one to ten hours before coming under my care and in all of them the infants have been born alive with the exception of one in which the arm had protruded for ten hours and was then quite black from congestion and in which the infant gave but a few spasmodic movements after delivery.

Bournemouth.

LEAD POISONING IN AN INFANT FOUR WEEKS OLD.

BY FREDK. W. M. STEPHENSON, M.B., C.M. EDIN.

I VENTURE to think that the particulars of this case—unique as far as my experience goes and, I believe, at least uncommon in that of others—may be of general interest. On Oct. 10th, 1898, I attended a patient in confinement. The child was well nourished and healthy and continued so until the end of my visits about a week afterwards. On Nov. 8th I was hurriedly sent for, the message stating that the infant was dying. I was informed by the mother on my arrival that the child appeared to her to be just recovering from a fit. I found the patient evidently in considerable pain, screaming violently, and with the legs flexed upon the abdomen. My first and most natural conclusion was that these symptoms indicated colic due to imperfectly digested food, but on examining the tongue I noticed an unmistakeable blue line on the gums. This with a history of constipation was quite sufficient to confirm my diagnosis that lead was the cause of the trouble. The child had never taken milk from the breast, but the feeding bottles were, I found, above suspicion, as well as the water-supply and general surroundings. Finally I discovered that the nurse, considered an experienced woman, had been freely dusting the child with a powder, procured by herself quite innocently from a local chemist, and which was shown to me in a packet bearing the label "Powdered White Lead." This had been liberally dusted about the neck and behind the ears, and consequently would at such times be freely inhaled. In addition the powder had been kept loosely upon the mantelshelf where the feeding bottle and a "dummy teat" were frequently placed.

I am pleased to be able to add that under the usual treatment, modified to suit the age, the child is making a good recovery.

DERBYSHIRE ROYAL INFIRMARY.

A CASE OF CEREBRAL TUMOUR; NECROPSY.

(Under the care of Dr. G. H. MILNES.)

THE success which often attends attempts to localise cerebral tumours is remarkable, but it not infrequently happens, as in the very interesting case reported below, that the data presented by the signs and symptoms are not sufficient to allow any exact diagnosis to be made. The presence of more than one growth increases largely the difficulty; great extension of the growth has a similar effect. In the following case the most striking point is the interference by the tumours with the intracranial venous circulation, leading to dilatation of the collateral vessels. For the notes of the case we are indebted to Dr. H. M. Tickell, house physician.

A man, aged twenty-eight years, a railway guard, applied for treatment at the Birmingham Eye Hospital on May 3rd, 1897, on account of failure of sight, and on examination was found to have double optic neuritis. The first symptom noticed by him, ten weeks previously, was severe pain in the head. Shortly after this he had vomited for some weeks and had pain down the left side of the face, the pain passing off when the sight began to fail and being succeeded by numbness. The only history of previous illness obtained from him was an attack of small-pox three years previously, and syphilis was denied. On the 17th the knee-jerks were found to be exaggerated. A few days later he began to have attacks of vomiting without relation to food and he also complained of pains in the head and at the root of the nose. On June 21st he was admitted as an in-patient of the Derbyshire Royal Infirmary. It was then observed that the plantar reflexes were greatly increased. As regards vision, he had but a bare perception of light, the discs passing into atrophy. He was discharged from hospital on July 10th. There had been no headache or vomiting since his admission and he described himself as feeling much better. On the 14th he came again to the hospital as an out-patient. The next symptom of importance which was noticed was an enlargement and varicose condition of the veins in the frontal region about the middle line. A short time afterwards a similar prominence consisting of a bunch of dilated veins appeared above the external occipital protuberance. On the occurrence of severe headache these veins were observed to become more swollen, thus indicating that the headache was due to increased cerebral pressure. On Nov. 15th he was re-admitted into the hospital. He was then quite blind from optic atrophy. There were occasional occipital headache and continual numbness of the left side of the face and all round the mouth. He also had pain in the eyes, especially the right eye. On Dec. 4th there were

Digitized by Google

frequent occipital headache and vomiting and increased varicosity of the frontal and temporal veins. He was again discharged on Jan. 8th, 1898, but on March 11th he was admitted into the hospital for the third time suffering from much vomiting and headache. The next day he had an attack of convulsions and was unconscious for twenty-five minutes. These convulsions were at first general, but towards the end of the attack the features were drawn to the left side. He afterwards complained of pain all down the left side. On April 22nd he was strange in manner and he passed urine unconsciously. The varicose veins, especially those at the back of the head, were much swollen. He was again discharged on June 10th. On August 1st the sense of smell was found to be absent, and, becoming worse, he was again admitted to the hospital on Sept. 10th. He was found to be very much weaker and more wasted than when he was last in the hospital. He frequently rambled and muttered but was at times quite conscious and was able to answer simple questions. The lips and both sides of the face and forehead with the front of the tongue and the hard palate were insensitive to touch. An examination of the eyes showed paralysis of the orbicularis, the conjunctivæ were inflamed, hazy, and quite insensitive, but some movements of the eyeballs were noticed. The mouth was always half open and there was double facial paralysis. There was no paralysis or anæsthesia of the limbs, the knee-jerks were excessive, and the plantar reflexes were greatly exaggerated. On Sept. 21st his head was found to be turned stiffly to the left. The left forearm was flexed and kept close against the chest. No movement of the arm was seen. Death occurred on the following day.

Necropsy.—At the post-mortem examination the body was found to be emaciated. Visible grooves in the calvarium marked the course of the dilated veins which had been observed during life in the frontal and temporal regions. The occipital veins were engorged. The scalp adhered to the bone more firmly than in a normal condition; and there was a thickening of the connective tissue under the situation of the frontal mass of veins. The skull was thinned in three places—in the frontal region and at one spot on each parietal bone. These spots corresponded to the prominences of the convolutions under the dura mater, which structure was somewhat adherent at those points and engorged with blood. The absorption of skull in the frontal region corresponded to a large solid mass occupying the greater part of both frontal lobes—two-thirds of the mass occupying the right frontal lobe and one-third the left. The falx cerebri in this region was involved in the growth and was unremovable. The fissure of Rolando and the ascending frontal convolutions were uninvolved on either side. The other frontal convolutions could not be recognised. There was great varicosity of the veins of the whole vertical region, one special prominence on each side corresponding with one of the thin spots on the parietal bones, and at these points the varicose veins inside and outside the skull appeared to communicate. The whole brain substance was hyperæmic, the venæ Galeni being especially enlarged and varicose. The right lateral sinus was full of clot, in some places partially organised and softly adherent to the lining membrane of the veins, which at those points was roughened. The superior longitudinal sinus was not obliterated at any point, but at one spot about 1½ in. posterior to the tumour its lumen was markedly contracted, apparently from old inflammatory thickening. The origin of the inferior longitudinal sinus was completely obliterated by the growth, but its central portion was open and contained no blood or clots. The lumen of this sinus at its junction with the straight sinus appeared to be entirely obliterated by an old inflammatory thickening. This thickening appeared to involve the mouths of the venæ Galeni, for a fine bristle could not be passed from the veins into the sinus. Along the superior longitudinal fissure the membranes were softly adherent in many places which seemed to correspond to the areas where the varicose veins were most marked. The ventricles of the brain were normal excepting the right lateral ventricle, the anterior horn of which was greatly enlarged and ran forward round the outer border and underneath the growth and even in front of it, being in close relationship with a cyst in the substance of the growth which contained about two drachms of fluid and did not communicate with the ventricle. The veins of this right lateral ventricle were very much enlarged. The olfactory nerves were flattened and the olfactory lobes were atrophied, apparently from pressure. A portion of the tumour was sent to the Clinical Research Association and the following report upon it was made: "This tumour is composed of interlacing bundles of spindle-shaped cells with large areas of hyaline change between the bundles. It is certainly a sarcoma, but with a very low degree of malignancy." Under a $\frac{1}{12}$th objective distinct traces of fibrous structure could be discerned in the substance between the bundles. Several small cysts were found in the tumour.

Remarks by Dr. TICKELL.—In the above case we were fortunate in obtaining the records of observations almost from the first-noticed symptom, and the effects of the gradual extension of the disease up to its fatal termination can be followed. The diagnosis of "cerebral tumour" was made with some confidence at quite an early stage, but the question of localisation was complicated by the fact that the symptoms did not appear to be capable of explanation on the supposition of a single tumour, and even the result of the necropsy did not supply an entirely satisfactory solution of the problems involved, but it was nevertheless instructive. During life there was no question as to the presence of a cerebral tumour, but it will be gathered from the history that its situation could not be ascertained with sufficient precision to allow of any suggestion of an operation for its removal. It has been mentioned in the notes that severe pain was frequently complained of in the occipital as well as in the frontal region, and therefore this case bears out the observation that no deduction as to the site of a tumour in the brain can be drawn from the position of the headache. In considering the localisation of the tumour the following important features required explanation: 1. The presence of dilated veins in the scalp which formed especial prominences about the middle line. This condition pointed to obstruction in the longitudinal sinuses and the consequent establishment of a collateral venous circulation. The necropsy showed obstruction at the commencement of the sinuses and also at the posterior part of the inferior longitudinal sinus; it is probable that the latter had the most important effect in impeding the venous flow. 2. Paralysis of nerves. The fifth nerve was partially paralysed early and the seventh nerve later in the case. The olfactory nerve was probably paralysed a considerable time before the discovery was made. Paralysis of the third nerve in the later stage could not be definitely excluded; it was probably involved to some extent, but it was naturally difficult to test accurately the action of the various muscles of the eye. The loss of the sense of smell—an important localising symptom—was doubtless caused by pressure of the tumour on the olfactory bulbs and nerves. The explanation of the paralysis of the previously mentioned nerves was the main difficulty of the case. It is perhaps possible that some minute changes had taken place in the pons about the region of the nuclei of the fifth and seventh nerves in connexion with the altered venous conditions, but there is no direct evidence on this point; and, indeed, the character of the facial paralysis pointed rather to involvement of the seventh nerve after leaving its nucleus. On the whole, then, it seems most probable that these nerves were paralysed in consequence of the general increase of intracranial pressure, of which there was abundant evidence, although at the same time the reason why other nerves escaped the same fate cannot be stated.

LEEDS GENERAL INFIRMARY.

A CASE OF HÆMOPHILIA; OXYGEN INHALATION; RECOVERY.

(Under the care of Mr. W. H. BROWN.)

IT would be difficult to furnish a more typical family history of hæmophilia than that recorded below; and that alone would have justified its publication, but the success of the treatment employed was so striking that it is worthy of a more extended trial. Although the disease has been known nearly a hundred years, having been first observed in 1803 by Dr. J. C. Otto,[1] yet the treatment is usually very unsatisfactory. Of recent years the two most valuable suggestions have been chloride of calcium and extract of the thymus gland. The use of the former was based on the physiological fact that the presence of a calcium salt is

[1] Medical Repository of New York, 1803.

Digitized by Google

necessary for coagulation to occur, and it is said that it has been found of use; in employing it, however, it must not be forgotten that excess of calcium salts will prevent the occurrence of coagulation. The extract of thymus gland was recommended on the ground that, as Wooldridge showed, the injection of it into the blood-stream of an animal causes almost instantaneous death by intravascular coagulation; therefore this also must be used with caution, but it evidently possesses great influence over the coagulability of the blood. Mr. Brown's use of oxygen by inhalation is new to us as a remedy in hæmophilia, but after this striking case it should certainly be given a trial. For the notes of the case we are indebted to Mr. E. J. A. Dodd, house surgeon.

The patient, a boy aged thirteen years, was admitted into the General Infirmary, Leeds, on Nov. 6th, 1897, with a large swelling on the outer side of the right thigh. A fortnight before he had "sprained" his thigh whilst getting into bed. The family history was as follows. The patient's mother had had 14 children, 7 boys and 7 girls; 6 of the boys were dead, the mother stating that all died from bleeding. The girls were all alive and well; two were married and had borne children. The patient's uncle on the mother's side died from bleeding from the stomach; an aunt also on the mother's side had a son who died at the age of fourteen years from bleeding. The patient's personal history was that he had had many swellings in his joints following slight injuries. He had bled from the gums and nose many times. He had been an in-patient on three former occasions—namely, in 1894 for bleeding from the roof of the mouth following a prick with a pin, in 1896 for bleeding from the gums after a fall, and early in 1897 for hæmorrhage into the knee-joint from a slight accident. On admission the patient was found to be a fairly well-grown boy, but very anæmic. On the outer side of the right thigh there was a large fluctuating swelling, tender to the touch; the skin over the swelling was red and very thin. As it seemed to be likely that the skin would give way a fine aspirating needle was introduced and about 4 oz. of bloody fluid were withdrawn. A firm pad was applied over the swelling. Internally iron was given and the diet included green vegetables and fresh fruit. During the next three weeks the aspirator was used several times, but the swelling refilled. Then a small incision was made through the skin and a quantity of clot and some purulent fluid escaped. Firm dressings were applied, but these quickly became soaked through and the continual oozing kept on in spite of packing and pressure and the free administration internally of styptics. The boy grew rapidly weaker, his digestive powers failed, and vomiting commenced and continued. Bleeding from the nose and gums took place. The pulse was about 140 and the temperature was subnormal. As it seemed to be useless to continue the ordinary treatment, and as, moreover, the stomach rejected everything, it was decided to try the effect of inhalation of oxygen. This was given in large doses and within twenty-four hours the vomiting and bleeding had ceased and the boy was able to take milk freely. The further progress does not need much comment. The inhalation of oxygen was continued for a week, during which time no medicine was given. Later the patient was put upon iron. The wound in the thigh healed without trouble. The boy made a complete recovery and is now well.

Remarks by Mr. BROWN.—In recording the above notes I desire to obtain the experience of others who may have tried the effects of oxygen in similar cases. I have had to treat several hæmophiliacs, but I have never seen one so near death recover. I am aware that by some it is held that hæmophiliacs bleed to a certain point and then stop. The family history in the present case does not support this view, for the patient's six brothers bled to death. I have always had the idea that hæmophilia and purpura were closely allied—i.e., that both conditions were due to a lack of oxygen in the blood and that hæmophilia was purpura in its worst form. Acting on this idea I determined in the above case to try the effect of giving large doses of oxygen to the apparently dying boy and I think the result is sufficiently good to warrant the further use of oxygen in like conditions. I am not prepared to discuss the physiological effect produced. I merely record clinical facts and on these facts I suggest that the remedy is worthy of use in cases where the ordinary means to arrest the bleeding have failed.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Discussion on the Value of Pressure in the Treatment of Wounds.

A MEETING of this society was held on Nov. 28th, the President, Mr. OWEN, being in the chair.

Mr. A. PEARCE GOULD opened a discussion on the Value of Pressure in the Treatment of Wounds. He remarked that the importance of securing asepsis had revolutionised surgical procedure and had shown the small part played by other measures in securing or in influencing the perfect repair of a wound. It was very easy for the surgeon to overvalue the part he played in the processes worked out in nature's human laboratory, when sometimes he was actually hindering them. Ambroise Paré was splendidly right when he insistently urged that it was the good God who healed wounds. There was a tendency to insist on details which were not of real importance and to drop unconsciously into a thoughtless routine. The maintenance of one position for days, for instance, so contrary to the wont of nature, was an exaggeration of a wise desire to secure rest and was greatly overdone. The unthinking routine prescription of alcohol for nearly every physiological and pathological state was another illustration of the tendency. In reconsidering his views with regard to the value of pressure Mr. Gould now held that it was largely ineffectual for the purposes for which it was employed, that it was sometimes mischievous, and that it could be well and safely dispensed with. Pressure was usually employed to secure apposition of the edges of the wound, to prevent oozing, to lessen serious exudation, to prevent bagging of fluid, to restrain muscular contraction, or to prevent the yielding of cicatrices. But for some time past he had abandoned the use of pressure for these purposes and the wounds had healed better and the comfort of the patients had been promoted. For pressure was not always harmless, and without due care might cause sloughing where there was a large flap, as after removal of the mamma. He had also been struck with its inutility in certain cases, as where the edges united but fluid collected beneath the flap. Pressure did not prevent its re-accumulation, but the insertion of a drainage-tube removed the difficulty at once. Similarly he referred to the inefficiency of pressure where there was bagging of pus, a condition for which counter-opening had to be resorted to. Where ill-effects were avoided he believed that the good results were independent of the employment of pressure, since he was able to obtain equally good results by means of a firm collodion dressing. Mr. Gould held that pressure need not be resorted to even after such operations as excision of the mamma. Again after laparotomy for removal of large ovarian cysts or for hysterectomy a simple collodion dressing over the wound was better than the mountains of cotton wool and firm bandage which were still largely used. What surgeons had been in the habit of attributing to their therapeutical measures had been the result of nature's kindly offices. The comfort of his patients had been greatly increased by his ceasing to apply pressure.

The PRESIDENT said that Mr. Pearce Gould's paper was novel and raised many important points. The disuse of pressure would certainly add to the comfort of patients, but he would like to be quite convinced that it would be safe to discard it. He had lately removed a large cystic kidney, afterwards applying firm pressure. Would Mr. Gould refrain from doing so in such a case as that, where there was a large actual cavity left and not a potential one? He would also like to hear from Mr. Gould whether he advocated the return to the use of the drainage-tube.

Mr. ALBAN DORAN said that four or five years ago he left off strapping the abdominal wall after ovariotomy and relied on slight pressure with a many-tailed bandage and later he scarcely used any pressure at all, but he had returned to the use of pressure as be believed that tolerably firm pressure favoured the expulsion of flatus and encouraged intestinal movement and so hindered the formation of adhesions. The bandage should be employed so as to compress the abdomen as high as the epigastrium or flatus was apt to be imprisoned in the transverse colon.

Mr. STANLEY BOYD said that he also had observed the failure of pressure to prevent the accumulation of fluid, and

Digitized by Google

in certain places, as in operations on the thyroid gland and for the removal of glands from the neck, efficient pressure could not be maintained. With regard to the abdomen he thought that pressure was employed to prevent the intestine from becoming flaccid and distended. Probably, however, it was not necessary for the purpose of preventing dilatation of the abdominal veins. He also employed collodion, sometimes applying it on a piece of gauze a foot square. To prevent bagging he also employed the buried suture which had proved so useful in perineorrhaphy. It could not be used in some positions, as, for instance, near the deep vessels of the neck.

Mr. MARMADUKE SHEILD said that he did not think that any one method of dealing with wounds was of universal application, and though he agreed with much of the paper he still thought that there were many conditions, such as removal of the mamma and inguinal colotomy, where moderate pressure was called for, in the latter instance to prevent extrusion of viscera if there should be severe vomiting. As supporting Mr. Gould's contention he mentioned that he had seen in the practice of the late Sir George Humphry amputation wounds treated by the open method without any dressing whatever and had been struck with the ease with which they healed.

Mr. F. C. WALLIS was also inclined to take a middle course. No doubt the pressure employed was often excessive and in some positions it could not possibly exert much effect. He agreed with Mr. Boyd as to the value of buried sutures in preventing bagging, as, for instance, after operation for the radical cure of hernia.

Mr. PEYTON BEALE said that one object of pressure was to keep the dressing in position, and it was best effected by an elastic webbing bandage. The evil effects of excessive pressure were well seen in cases of excision of joints. He had repeatedly observed that those which were firmly bandaged did not do so well as those which were left loosely confined.

Mr. PEARCE GOULD, in reply, said that he had not taken up the wide ground of the treatment of wounds but had confined his remarks to the effects of pressure. He had gone back to the use of the drainage-tube in many cases, which should be left in for twenty-four or forty-eight hours and should then be removed. He often employed buried sutures for subcutaneous tissues but not often for deeper structures. He did not agree with Mr. Doran's views that pressure favoured the passage of flatus, and the cases which he had left with only a collodion dressing had had no more trouble in this respect than those former cases in which he had applied firm pressure. Even in the case of inguinal colotomy to which Mr. Sheild had referred pressure could not prevent expulsion of the viscera, as in the act of vomiting the abdominal muscles contracted and there was a space left between the bandage and the abdominal wall. He thought it possible that in some cases pressure might favour serous accumulation, as it would only act effectively on the veins and would probably not arrest the arterial flow.

The PRESIDENT announced that in connexion with the recent report of a case of recovery from sarcoma after the injection of Coley's fluid[1] one of the microscopists to whom the specimen had been entrusted had some doubts as to its sarcomatous nature. The question was referred to a subcommittee for examination and report to the society.

CLINICAL SOCIETY OF LONDON.

Green-coloured Urine.—Operative Treatment of Gumma of the Liver.—Laparotomy for Gastric Ulcer.

A MEETING of this society was held on Nov. 25th, the President, Mr. LANGTON, being in the chair.

Dr. H. M. FLETCHER read a paper on the Occurrence of Green-coloured Urine in a girl, aged twelve years. The source of the pigment was not discovered. The urine was acid and contained a large quantity of indican. On filtration blue pigment granules were obtained. The urine on standing deposited greenish-blue uric acid crystals. At first it was thought that this was an instance of an extremely rare condition—indigo in an acid urine. Spectroscopic examination showed, however, that the pigment was not indigo but methylene blue. Another almost precisely similar case occurring about the same time was also quoted, in which the pigment likewise proved to be methylene blue. Experiments made with methylene blue taken by the mouth proved conclusively the nature of the pigment. It was pointed out that the spectrum and reactions of methylene blue located in the urine differed markedly from those of an aqueous solution of the same body, some compound being probably formed in the urine.—Dr. A. E. GARROD thought that although no history could be obtained to account for its presence there was no doubt that the colouring matter present was methylene blue. In the very rare instances in which he had met with green urine the colouration had been caused by the spontaneous separation of indigo, which might sometimes occur as a dark or even black deposit.

Mr. W. G. SPENCER described three cases of Gumma of the Liver in which relief followed operative measures. The cases suitable for such treatment were exceptional, being those in which there was a single gumma of the surface or edge and where the liver was still unaffected by cirrhosis. An exposure of the tumour allowed a definite diagnosis to be made and so a course of anti-syphilitic remedies could be instituted. The first case was that of an unmarried woman admitted under the care of Dr. Allchin to the Westminster Hospital, in whom there slowly developed a tumour, apparently connected with the kidney. On exposure a gumma of the free edge of the liver was discovered which had become united by adhesions to the abdominal wall and which was overlapped by intestines. The mass was fixed in the wound, the interior was scooped out, and the cavity was filled with gauze. Healing rapidly occurred under anti-syphilitic treatment. The second case was that of a widow, thirty-three years of age, admitted under the care of Dr. de Havilland Hall, who had become ill a year before with enlargement of the liver, slight jaundice, ascites, and wasting. She was repeatedly tapped, but the fluid re-accumulated so quickly that she became exhausted. Drainage was resorted to and at the operation a digital exploration was made, which showed that there was no malignant disease but some cirrhosis of the liver and a small gumma on the free edge. Iodide of potassium and mercury were therefore freely administered and the patient improved greatly and left the hospital convalescent. But a complete restoration to health seemed impossible on account of the cirrhosis. The third case was that of a middle-aged woman seen ten years ago with Dr. Ferris of Uxbridge. She had a large tumour growing from the liver, which was about to ulcerate through the skin. In view of the fact that it would practically be impossible for a patient with cancer of the liver to survive until the growth had fungated through the skin the mass was cut into and gummatous sloughs were scooped out. The woman, being thus freed from the effects of septic absorption and being treated with anti-syphilitic remedies, rapidly regained good health and had remained so ever since. Mr. Spencer also referred to the removal of pedunculated gummata.—Mr. CLEMENT LUCAS related the case of a girl, twenty-one years of age, who had a mesial tumour in the epigastrium obviously connected with the liver. As on exploration this had the appearance of a gumma the wound was closed and the patient was treated with iodide of potassium and entirely recovered. In another case, that of a woman, thirty-eight years of age, the patient had an enlargement of the abdomen for over two years. In April, 1898, a large nodular tumour connected with the liver could be felt extending down to the umbilicus. On exploration the whole surface of the liver was cicatricial. There was no definite history of syphilis, but she improved greatly under iodide of potassium.—The PRESIDENT related a similar case, also in a woman, to whom, instead of operating, he gave iodide of potassium on the chance of the enlargement being syphilitic and the tumour disappeared.

Mr. F. C. WALLIS read notes of two cases which he had operated on for the effects of Gastric Ulcer. The first case was that of a young woman, aged twenty years, who was admitted to the Metropolitan Hospital on March 11th, 1898, for a perforated gastric ulcer. The patient was operated on ten and a half hours after perforation. On opening the abdomen the contents of the stomach were found extravasated chiefly in the gastro-hepatic area. The rent was in the posterior wall, close to the cardiac end, and nearly 1 in. in length, and was sewn up by two rows of Lembert sutures, and a piece of omentum was sewn over the line of suture. The abdomen was wiped out with sponges but no irrigation was employed and no drainage was used. The patient did well for eleven days and had no peritonitis. On the eleventh day she developed phlebitis. On the

[1] THE LANCET, Nov. 19th, 1898.

Digitized by Google

seventeenth day basal pneumonia occurred, which continued until the twenty-ninth day, when the temperature came down and she began to improve. But on the thirty-first day she vomited suddenly 6 oz. of blood and died within an hour. Permission for a necropsy was refused. Mr. Wallis remarked on the cause of death by hæmorrhage thirty-one days after the operation as being unusual and unfortunate. He suggested that it might be advisable in many cases to enlarge the opening sufficiently so that an examination of the interior of the stomach might be made and that a small electric lamp would be of great service in such cases. The fact that, although the peritoneum was only wiped clean and not irrigated, there was no peritonitis was in keeping with the now well-known resisting powers of the peritoneum. Mr. Wallis had been led to adopt this method on account of the frequent occurrence of subphrenic abscesses after irrigation. The second case was that of a young woman, a patient under the care of Dr. Fincastle Clarke, who was seen first in July, 1896. The history dated from December, 1882, when she had an attack of gastro-enteritis which recurred repeatedly until November, 1895, when on getting out of bed she was suddenly seized with the typical signs of a perforated gastric ulcer. From this she recovered but from that time until the operation she was unable on account of pain to take any exercise and was only able to take fluid food in small quantities at a time. On examining the patient she was seen to be extremely emaciated and weak and the abdomen was tender when manipulated, especially above and to the right of the umbilicus, where there was a distinct sense of resistance. Dr. Abercrombie and Dr. Clarke saw the patient with Mr. Wallis and it was agreed that an exploratory laparotomy should be done. At the operation a strong band ¼ in. broad and 1¼ in. long was found issuing from the pyloric end of the stomach to the abdominal wall. This was removed. The patient made a complete recovery after a long convalescence and was now able to enjoy life after fourteen years of invalidism. The pain had never returned and she had put on flesh and was able to take exercise, and as it was now two years since the operation there were fair grounds for believing that the benefits would be permanent.—Dr. FRANCIS HAWKINS (Reading) related the case of a young woman suffering from gastric ulcer with masked symptoms. Signs of perforation suddenly developed and she was operated on and recovered. He did not feel certain that laparotomy should be performed at once in all cases as he recalled two cases in which the evidence appeared to show that perforation had occurred but in which spontaneous recovery took place.—Dr. KINGSTON FOWLER also thought that rarely patients might recover without operation and mentioned the case of an ex-soldier who had long been suffering from symptoms of gastric ulcer and one day became collapsed with symptoms of perforation. The next day he had abdominal distension with disappearance of liver dulness. Operation was proposed but he refused to submit, and to Dr. Fowler's surprise he recovered, the liver dulness gradually returning to normal. Notwithstanding the fortunate result in this instance, however, he thought that in such grave cases operation should be advised.—Dr. SIDNEY PHILLIPS had had a series of cases of gastric ulcers under his care during the last few months. In two he believed that perforation occurred and both recovered without operation. In a third case laparotomy was successfully performed. In the first case there were the usual symptoms of perforation and disappearance of the liver dulness. The patient was fed by the rectum for some time and improved, but as soon as food was given by the mouth the symptoms recurred and the liver dulness again disappeared, but ultimately she got well. The ulcer was probably in the posterior wall. In another case, occurring in a girl eighteen years of age, the pain was so acute at first that he thought that it could not be due to perforation, especially as the liver dulness was normal. Two days later there was evidence of local peritonitis and the liver dulness disappeared. As the pulse was good and there was no acute vomiting he had not advised operation and she was now recovering.—Mr. W. G. SPENCER suggested that in some cases the disappearance of liver dulness was due to distension of the colon, and mentioned a case in which there was marked distension of the colon, which was found after death to have been due to a kink caused by an adhesion connected with a duodenal ulcer. He had recently met with another instance during an operation for pyloric obstruction. A fibrous band extended from the pylorus to the colon and caused the distension. Unless the disappearance of hepatic dulness was accompanied by a very rapid pulse he did not think it was of much importance. In cases of perforation the pulse-rate was rarely below 120.—Dr. LUCAS BENHAM related the case of a middle-aged stout woman who was taken suddenly ill with diarrhœa and intense abdominal pain. She improved for a time but soon relapsed, the stools containing mucus and pus. She ultimately died and at the necropsy it was found that an ulcer of the size of a shilling on the posterior wall of the stomach had ruptured.—Dr. TOOGOOD mentioned a case in which disappearance of the liver dulness was noticed without perforation occurring. The patient was a blacksmith who had been under treatment for gastric ulcer. After dinner one day he was seized with acute abdominal pain and vomiting and was admitted into the Lewisham Infirmary in a state of collapse. As the liver dulness had entirely disappeared Dr. Toogood cut down on the stomach, but finding that its contents had not escaped he stitched up the wound. At the necropsy he found a very small aneurysm of the arch of the aorta which had ruptured. The pulse-rate was between 130 and 140. He could not give any explanation of the disappearance of the liver dulness.—Mr. CHARTERS SYMONDS narrated the case of a woman, sixty years of age, who had suffered for twenty-five years from symptoms suggestive of gall-stones, but there were also symptoms of obstruction at the pylorus with dilatation of the stomach. On exploration he found a very large stomach with a thick mass in the posterior wall narrowing the stomach into two parts. As this was taken to be malignant he united the cardiac portion to the small intestine by direct suture. On the fifth day she died suddenly, and at the necropsy the stomach was found to be filled with blood coming from an old gastric ulcer, of which the thick mass was the heaped-up border. On the posterior wall of the stomach there was an opening 5 in. wide leading into a large cavity. In a second case, that of a man forty-six years of age, there had been attacks of abdominal pain attributed to gall-stones for thirty years. On exploration the gall-bladder was found to be healthy, but there were many adhesions in the neighbourhood. Later there were symptoms of gastric dilatation and adhesions were found all round the pylorus and duodenum. In dilating it he ruptured it right through to the peritoneum. He sewed up the rent and closed the wound. In a third case, that of a girl, there was a history pointing to perforation of a gastric ulcer. There was a mesial swelling, and an incision gave vent to much foul-smelling pus from a cavity which reached up to the diaphragm. A large, thickened stomach was exposed, which he accidentally ruptured for a length of 3 in. This he sewed up and the patient recovered. With regard to the desirability of operating in every case it must be borne in mind that the diagnosis was not always perfectly clear. In one case the operation was postponed for a day, and the pain and vomiting were found to be connected with the onset of an attack of acute pneumonia, and in one which was operated on the stomach was found to be perfectly healthy, the vomiting being apparently hysterical. He did not quite agree with Mr. Spencer's views as to the pulse-rate. It was not necessarily rapid in perforation: in his first case it was 60, and cases had been recorded in which it was only 30.—Mr. WALLIS, in reply, observed that while it might possibly not be advisable to operate in every case there was no doubt that many patients died for want of timely operation, and the risk of the operation was slight as compared with that of an untreated perforated ulcer.

HARVEIAN SOCIETY OF LONDON.

Functional Dysphagia.

A MEETING of this society was held on Nov. 17th, the President, Dr. J. F. GOODHART, being in the chair.

Dr. STCLAIR THOMSON read a paper on Functional Dysphagia which will be found in full at p. 1463 of our present issue.

Dr. C. S. JAFFE remarked that dysphagia of neurotic origin and not associated with other symptoms of hysteria was as common in men as in women.

Dr. DUNDAS GRANT complimented Dr. StClair Thomson and stated that in his cases of functional dysphagia paralysis of the œsophagus was relatively more frequent than it appeared to have been in Dr. Thomson's. He (Dr. Grant)

Digitized by Google

diagnosed it by the abnormal ease with which a very large indiarubber œsophageal tube could be passed. He referred also to cases of reflex spasm of the œsophagus simulating malignant disease and arising either from malignant disease in the abdominal organs or from defective dentition. In reference to electricity he had learnt from Dr. de Watteville how to bring about forced movements of swallowing by the continuous current, the positive pole being placed on the nape of the neck and the negative one being drawn gently down the side of the neck between the sterno-mastoid muscle and the trachea. Before introducing the bougie he made it a rule to assure himself that the cardiac apex beat was in its normal position. In the passage of a bougie in the middle line the cricoid cartilages sometimes acted as an obstruction, and in such cases the instrument could often be passed with ease if introduced to one side or other of the middle line. This was more readily done with a round than with a flat bougie, and he found in some cases a large bougie with a radish-shaped end preferable to a flat one.

Dr. CLIFFORD BEALE referred to three cases of functional dysphagia where the patients appeared to be almost unable to swallow in the presence of an onlooker but could take food without difficulty in solitude. The sensation of constriction of the gullet sometimes led to the suspicion and even to the diagnosis of cancer, but the passage of a large œsophageal bougie by demonstrating the absence of any stoppage not unfrequently caused the disappearance of the sensation. A very small inflammation of a follicle in the pharynx might produce a very considerable dysphagia, and he suggested the possibility that some cases of transient dysphagia might be due to a similar cause situated in the œsophagus itself.

The PRESIDENT alluded to the not uncommon inability of children to swallow solids. Sometimes this inability persisted up to the age of two or three years. In some cases it might be due to adenoids, but he believed that it was usually dependent on some functional neurosis. He mentioned a case in which dysphagia was caused by phlegmons of the œsophagus. He had met with an instance in which a man had been unable for many years to swallow except with great slowness and in small sips. Possibly congenital narrowing of the lower part of the œsophagus existed here, but he inclined to the view that the inability was functional. Functional dysphagia was occasionally mistaken for that caused by cancerous stricture, but the converse error had been known to occur. He regarded aneurysm as an extremely rare cause of dysphagia. He attached great value to auscultation as a means of diagnosing œsophageal stricture.

Dr. G. A. SUTHERLAND thought the passage of an œsophageal bougie was of value in some cases of functional dysphagia. He recalled one case in which a patient was unable to swallow owing to the presence, as he believed, of a pill in his throat. The passage of a bougie was immediately followed by the disappearance of the dysphagia. He agreed with Dr. StClair Thomson in the importance of making a thorough examination of the naso-pharynx and larynx both visually and digitally. In the case of a small foreign body such as a fish bone he had found by experience that after localising the part by the patient's sensations a careful examination of that region with a probe would probably reveal a point of extreme tenderness where the foreign body would be found.

After some remarks by Dr. H. J. MACEVOY,

Dr. STCLAIR THOMSON, in reply, said he was much gratified at the reception of his paper, for, as he mentioned in his introductory remarks, he had no new facts or ideas to submit. The paper had been the result of an effort in his own mind to get a clear conception of this affection. In doing this he feared he had talked all round the subject and had defined it chiefly by a process of exclusion. The debate had shown the protean features of hysteria. In his own experience the majority of patients had been females. A hollow bougie was doubtless much more comfortable for the patient and easier to pass, but the rigid tube for diagnostic purposes gave a good deal more information. If surrounded with every precaution doubtless the œsophageal bougie could be passed without danger, but there could be no doubt that dangerous accidents with it had happened in the hands of some of the most experienced and expert practitioners. The dysphagia associated with anæsthesia of the larynx, the pharyngismus associated with defective teeth, and the aphagia described by the President as occurring in infants and adenoid subjects, might, he thought, be classified under the heading of reflex dysphagia.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Grave Anæmia.—Effects of Frequent and Infrequent Feeding.

A MEETING of this society was held at the Royal Infirmary, Bradford, on Nov. 15th, the President, Dr. BERRY, being in the chair.

Dr. ROBSON gave a Microscopical Demonstration.

Dr. MAJOR showed a series of photographs of a Cretin under Treatment by Thyroid Extract.

Dr. CAMPBELL showed a Liver weighing 109 oz., a very marked instance of fatty and fibrous degeneration.

Dr. KERR showed (1) a specimen of Malignant Disease of the Larynx removed by Laryngectomy; and (2) a specimen from a case of Lateral Sinus Thrombosis.

Dr. GLADSTONE showed a patient and read notes on a case of Grave Anæmia which had been successfully treated with arsenic and general massage. The patient was a boy, thirteen years of age, a newspaper-seller, who had suffered much from privation and neglect. He was admitted to hospital on Oct. 6th, 1897, complaining of shortness of breath, cough, and abdominal pain. Examination of the chest showed that the heart's apex was displaced slightly outwards and there was a soft systolic murmur over the whole cardiac area. The lungs showed nothing abnormal. The urine contained a trace of albumin but no casts. The fundus oculi was normal. At the end of a fortnight the anæmia was extreme; hæmoglobin 30 per cent. Fourteen days later the patient was extremely weak and could hardly sit up in bed and his face was white and puffy. The blood was examined and was found to contain (Nov. 13th) 990,000 red discs per cubic millimetre and there were noticed numerous irregular-shaped discs. Neuro-retinitis was now discovered. During the preceding three weeks the patient had been taking iron with small doses of arsenic. This was now omitted and salol was given with a view to intestinal antiseptic treatment. After a slight improvement in the blood-count, he again became much worse and on Dec. 6th was apparently moribund. Blood discs, 624,000; hæmoglobin, 10 per cent. All food was returned. Rectal feeding was now begun. Ten minims of arsenical solution were given three times daily, together with general massage for twenty minutes daily. On Dec. 13th the patient was much better and was able to take food. Hæmoglobin, 20 per cent.; blood discs, 1,520,000. Retinal hæmorrhages were observed on Dec. 18th. On Dec. 22nd he had an attack of capillary bronchitis and he became very ill again. He steadily improved after. This complication had passed away and on March 5th, 1898, he was sent to a convalescent home. Hæmoglobin, 50 per cent.; blood discs, 3,090,000. By a mistake the patient walked all the way (about five miles) and was taken in much exhausted; he soon recovered however. When seen in June the boy had a good colour. Hæmoglobin, 80 per cent.; blood discs, 4,600,000, no irregular discs being seen. There was still a cloud of albumin in the urine. When shown to the medical society the patient was apparently quite well. The massage had been continued with some intermissions up to Feb. 21st, 1898, when it was no longer thought to be necessary. Dr. Gladstone remarked that after the massage the boy seemed to feel comfortable and to be refreshed. It appeared to induce sleep.

Dr. RABAGLIATI read a paper entitled "Some Effects of Frequent and Infrequent Feeding." He said that he had had a considerable amount of experience now in treating patients by recommending them to eat twice a day only in place of the three, four, five, or even six times frequently adopted. He believed that with a few exceptions, due to alcohol, syphilis, heredity, and the like, the main predisposing cause of nearly all the illnesses he had been in the habit of seeing for the last thirty years was too frequent and too abundant feeding. Death from starvation pure and simple no doubt could occur, and no doubt did occur, but he remembered only one case of it—in a neglected infant. He referred then to the exciting causes of disease, the ultimate difference between them and the predisposing causes consisting, he thought, in frequency, as distinguished from infrequency, of action. Next he referred to the proximate causes of disease which he would rather call "states" than "causes." There were two, and two only—shrinking and

Digitized by Google

swelling—and there was the intermediate state when swelling was passing into shrinking and shrinking into swelling. He criticised the terminology of Cœlius Aurelianus, contending that the terms used by him to signalise the proximate causes ought to have been not "strictura" and "solutio," but "strictura" and "dilatatio"; and that the state named "stricturæ et solutionis complexio" ought to have been 'stricturæ et dilatationis alternatio," since shrinking and swelling could not be combined in the same part at the same time but might alternate with one another and, in fact, must do so, since the succession of the one state on the other must occur owing to the very constitution of organisation—or at least always tended to occur. He then referred to the terminology introduced by Asclepiades of Bithynia, and proposed, instead of the acute and chronic diseases of that author which, he said, were not logical opposites, a classification into the œdemic diseases and the izamic, and said further that diseases were eilemmatous and parenchymatous and that the former might be endeilemmatous or exeilemmatous. For instance, pneumonia was a parenchymatous disease, bronchitis endeilemmatous, and pleuritis exeilemmatous. The confused views, as he considered them, of Sydenham were also considered and criticised, but he noted that Sydenham believed that gout was a disease due to "drinking and feasting." The view of Dr. King Chambers that 3 lb. avoirdupois was a reasonable daily average weight of food to be taken was unfavourably criticised, Dr. Rabagliati thinking that it was far too much and that Ranke's estimate of 100 grammes proteids, 100 grammes fats, and 250 grammes carbohydrates, in all about 1 lb. avoirdupois of mixed food, was far nearer the proper quantity. 3 lb., he thought, might, and in fact did, frequently produce starvation due to over-repletion. Cornaro lived to about 100 years of age on the daily consumption for about sixty years of ¾ lb. of mixed food. As examples of starvation due to over-repletion Dr. Rabagliati instanced callous ulcer of the leg, rheumatism, and cancer, saying that probably his views on this subject might collide with those of other members of the society. He then quoted cases and among the rest one of chronic vomiting in a man, aged forty-seven years, who had suffered for seven and a half years. His disease had, it was said, been variously diagnosed as cancer of the stomach, malignant growth of the stomach, chronic atonic dyspepsia, and chronic gastritis (the last being Dr. Rabagliati's own diagnosis). Various methods of treatment had been adopted without benefit. All kinds of gastric sedatives and tonics and frequent washing out of the stomach had been used, but without benefit. He had himself four years ago treated the patient but without more than transient relief. In these circumstances and considering the great length of time during which the case had persisted he recommended a long fast in order to see if stopping food altogether for a time would be followed by any relief. The suggestion was not at first favourably received by the patient, but after a time when, as he afterwards said, he thought himself dying at any rate, he expressed himself as willing to submit to it. The temperature under the tongue was 96° F. and at the commencement of the fast the weight was 130½ lb. In the first week the patient had only water, about a pint a day. For the eighth and ninth days he had besides water the whey from a pint of milk, the curds being separated by means of rennet. After the ninth day he had a daily allowance of whey from two pints of milk, no restriction being put on him as to water, which he took either hot or cold as he fancied. The patient never vomited or felt as if he would vomit since beginning treatment on Sept. 1st till the fast ended on Oct. 6th, neither had he vomited since. At the end of the fast the pulse was 65, soft, steady, and regular, and the temperature was 98·4°. He was up and about the whole time, helping his wife with light domestic duties. The weight of the patient at the end of the fast was 117¼ lb.; the loss of weight therefore was 13¼ lb., or an average of 6 oz. daily during the fast. Since the fast the patient had been eating ordinary food twice daily, taking a total weight of from 12 oz. to 16 oz. daily. If whey contains, as it is said to contain, about 7 per cent. of solids, then the patient would have had about 2 oz. of sustenance daily during the last four weeks of the fast, which would make the average daily loss of weight about 8 oz. had he lived entirely on his own material during the time. The paper concluded with some comments on the case and some observations on the kind of reasoning which led to the suggestion that a fast might be beneficial. In particular Dr. Rabagliati said that a patient might be in a low state of health and vitality because he had not sufficient food but that he might also be in that state because he was crushed by the load which he was carrying—as appeared to be the case in the instance detailed.—Dr. HIME criticised the paper and pointed out that Dr. Rabagliati had produced very little evidence in support of his statements. He regretted that no modern authorities on pathology had been cited.

The time at the disposal of the meeting having now expired the President declared the meeting at an end. It was decided by a vote of the members not to hold an adjourned discussion.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Specimens.

A PATHOLOGICAL meeting of this society was held on Nov. 18th, the President, Mr. EDWIN LEE, being in the chair.

Dr. ALLAN showed, among other specimens, a Foreign Body from the Peritoneal Cavity, a Syphilitic Tongue, and a Hypertrophied Tibia from a case of Chronic Ulcer of the Leg.

Dr. WARDROP GRIFFITH described and contrasted two specimens of Obstruction of the Inferior Vena Cava. In one the cause was aneurysm at the bifurcation of the aorta, with first pressure on, and then communication with, the cava. The superficial abdominal veins were greatly enlarged. In the second example, occurring in a man, aged fifty-five years, who died after an operation on the bladder, no symptoms were present during life. The obstruction was complete and just above the junction of the renal veins. In this instance the collateral circulation was carried on entirely without the assistance of the superficial veins of the abdomen, which was accounted for by the obstruction having occurred so early in development that the inferior cava had not fully taken on the duties of the cardinal veins which therefore remained as very large azygos veins.

Dr. EURICH showed: 1. Specimen and Microscopic Sections of a Tumour of the Kidney removed post mortem from a child, aged two years, and weighing 6¼ lb.; it was composed of small round-celled sarcomatous tissue, imbedded in which was embryonic gland-tissue. In its interior there was a hard nodule formed of embryonic striped muscle in different stages and a few well-defined clusters of cells, either epithelial or endothelial, probably the former. The growth was in parts angiomatous and contained many hæmorrhages. The tumour should be classed among the teratomata. 2. Sections from a "Perithelioma," a so-called "Psammoma," and a "Cylindroma" of the Brain. All three were really angio-sarcomata, the difference in their appearance being due to changes in their vessels, either in the direction of calcification or of hyaline degeneration. Both these changes may occur together. Calcification is preceded by an obliterative endarteritic process. 3. Specimen of Malignant Disease (? Sarcoma) affecting the Stomach, the Ascending and Transverse Colon and the Rectum, in a woman, aged twenty-nine years.

Dr. BRAITHWAITE showed a Cyst of the Great Omentum. This cyst occurred in a female child, four years of age. It occupied nearly the whole of the front of the abdomen. It was removed by operation in March of this year and was found to contain between 3 and 4 pints of clear, watery fluid. The cyst had walls about ⅛ in. in thickness when it was empty of fluid and its internal surface was speckled with patches having an iridescent colour like mother-of-pearl. These spots were more prominent than the rest of the surface. By keeping in spirit for eight months this appearance had been nearly lost, but it was still to some degree visible. In addition to this larger cyst there were several much smaller ones, none, however, larger that a walnut. The patient recovered and is now in good health. Two years previously the child's body was noticed to be very much bruised, but from what cause could not be ascertained. This may possibly have had some effect in originating the tumour. In support of this theory it may be remarked that billiard players are said to be liable to tumours of the omentum, at any rate, a paper was published a few years ago to point this out.

Mr. WHITE showed microscopic specimens of Lardaceous Disease of the Kidney, Liver, and Spleen.

Mr. LITTLEWOOD showed a series of Twelve Kidneys

Digitized by Google

removed either by lumbar or abdominal nephrectomy. The specimens included 3 of neoplasms, 3 of tuberculous disease, 2 of calculus and one of septic pyelo-nephrosis.

Dr. BARRS showed a specimen of Typhoid Ulceration of the Large Intestine from the body of a young woman who died in the fifth week of the disease. The lesions showed the various stages from a mere swelling of the solitary glands up to a commencing separation of the slough. There had been no relapse and the patient had never been able to take solid food. A specimen of Typical Typhoidal Broncho-pneumonia was also shown from the same case.

Dr. CHURTON showed a specimen of Sarcoma of the Pancreas from a case in which there was glycosuria.

Mr. W. H. BROWN showed a piece of Gangrenous Intestine removed from a strangulated hernia.

Dr. NUNNELEY showed a specimen of Degeneration of an Eye resulting from a foreign body resting on the retina for thirty years.

Mr. SECKER WALKER showed an Eye affected with Secondary Glaucoma.

Dr. NUNNELEY and Mr. WALKER also each showed a specimen of Intra-ocular Sarcoma.

Dr. TREVELYAN showed Sections from Eczema of the Skin, death being due to other causes.

Mr. MOYNIHAN showed a series of Photographs and Lantern Slides illustrating the Anatomy of the Duodenal Fossæ and Duodenal Hernia.

An extensive series of Coloured Drawings was exhibited by Dr. BARRS and Dr. TREVELYAN.

The specimens, some 60 in number, added to the Leeds Medical School Museum during the last eight months were also shown.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Ligature of the Left Subclavian Artery.—Coxa Vara.

A MEETING of this section was held on Nov. 11th, Mr. R. L. SWAN, the President, being in the chair.

The proceedings commenced with the delivery of the President's Address.

Mr. R. BOLTON M'CAUSLAND read notes of a case of Stab Wounds of the Left Shoulder necessitating Ligature of the Left Subclavian Artery on the Twenty-seventh day for Secondary Hæmorrhages. A shoemaker, aged thirty-four years, was admitted to Steevens' Hospital on Feb. 16th, 1898, with four stabs about the shoulder, one of which entered the posterior fold of the axilla. He was very blanched, but the wounds were stitched up and dressed first on the fifth day. Slight bleedings occurred on the seventh, eighth, ninth, and tenth days necessitating plugging of the wound; these ceased till the eighteenth, nineteenth, and twenty-first days; then there was a profuse hæmorrhage on March 13th. Two days afterwards three courses seemed to present themselves: (1) amputation at the shoulder; (2) ligature of the subclavian artery; and (3) enlargement of the wound and search for the bleeding vessel. The latter procedure was first adopted, but profuse bleeding then came on; the wound was plugged with turpentine compresses and the subclavian artery was tied on the same side with silk. There was no bleeding from the date of operation; the subclavian wound healed at once under two dressings; the axillary wound was dressed on the second day and under a daily dressing granulated rapidly, healing on the thirty-eighth day. Wild, uncontrollable delirium came on in forty-eight hours after the operation and lasted nine hours; opium enemata and bromides seemed of use; it passed away as rapidly as it came on. The temperature remained normal from the second day, the man made a good recovery, and was out of bed on the twenty-fifth day. Morphine, arsenic, and quinine were used to combat pains in the shoulder, arm, forearm, and hand; massage was also of great benefit. At present the man is in good health and he has almost complete movement in the shoulder, but cannot hold his work in his left hand for more than two hours. The temperature in both hands is the same, though he complains of the left being colder. Radial pulsation appeared feebly on the thirty-fourth day after operation and has not increased. The wounds are all soundly healed.—The case was discussed by Mr. HENRY GRAY CROLY, Mr. T. MYLES, Mr. CHANCE, and Mr. LENTAIGNE.

Sir THORNLEY STOKER read a paper on Coxa Vara in which he referred to the history of the discovery of the complaint and to the fact that until 1889 it had been mistaken for morbus coxæ. The deformity was most commonly due to rickets. It was a condition of bending of the neck of the femur so that the head of the bone was depressed, and shortening of the limb was thus produced. The head was also bent backwards so as to render the neck convex in front, and thus cause eversion of the thigh, which, combined with shortening, was the chief physical evidence of the disorder. He said that until 1896 he had been teaching that many mild cases of morbus coxæ occurred in which recovery took place with no defect beyond a little shortening; these were now known to be, for the most part, examples of coxa vara. The diagnosis of coxa vara from morbus coxæ was of importance, as the former condition was free from danger to life and must be treated on different lines.

SECTION OF PATHOLOGY.

Enchondroma of the Thigh.—Tubercle of the Eye.—Bicuspid Aortic Opening.—Aortic Stenosis.—Hypertrophy of the Heart.—Septico-Pyæmia.—Various Lesions of the Ulna.

A MEETING of this section was held on Nov. 4th, Dr. J. M. PURSER, the President, being in the chair.

Mr. JOHN LENTAIGNE read a communication on Diffuse Enchondroma of the Thigh.—Dr. E. J. MCWEENEY had made a microscopic examination which showed the characters of hyaline enchondroma extremely well. The central portion was composed of cancellous bone.

Mr. J. B. STORY showed Two Eyeballs removed for Tuberculosis, and Mr. O'SULLIVAN exhibited and described the microscopic appearances. One was a case of tuberculosis of the iris and ciliary body in a boy, aged seventeen years, presenting the ordinary characters. The other was a case of localised tuberculosis of the intra-ocular end of the optic nerve, simulating papillitis with detached retina. It occurred in a girl aged twenty-one years.—Dr. E. J. MCWEENEY said that no method of staining brought out the structural details so well as Von Gieson's. He thought that the reason why tubercles were not found in the retina oftener was, perhaps, because they were not sought for. As a rule the lesions of tuberculous eyes were more or less evident in front.

Dr. H. C. DRURY exhibited the Heart of a man, aged about fifty-five years, showing the rare anomaly of only two valves at the aortic opening. The condition of the heart during life was unknown as the patient was admitted into hospital in a dying state and only lived a few hours. There was atheromatous thickening of the aortic valves which rendered them incompetent; there was also atheroma of the aorta above them. The other valves of the heart were normal, the pulmonary opening having three normal healthy valves. Though there was atheroma of the aorta and its valve he considered that the bivalved condition was a congenital one and not acquired by the adhesion of two cusps and subsequent absorption or ulceration of their attachment to the aorta, because (1) the cusps were approximately equal in size and very large and (2) there was no evidence in either cusp of a line of union. Their position was, one to the right and slightly posterior, the other to the left and slightly anterior—the slit between their free edges being directed from before and a little to the right back and a little to the left. The one to the right appeared to represent the normal right posterior with half of the anterior cusp, the one to the left representing the normal left posterior with the other half of the anterior cusp. There was an opening of the coronary arteries behind each, that of the right coronary being situated behind the anterior part (corresponding to half of the anterior cusp) of the right cusp and that of the left coronary artery behind the posterior part of the left cusp.

Dr. J. B. COLEMAN exhibited five Hearts showing various lesions. In one, removed from a female, aged fifty years, the left ventricle was hypertrophied without dilatation; the aortic valve was stenosed to a mere sinuous chink; the anterior and left posterior segments were fused, thus producing a bicuspid aortic valve; the segments were sclerosed and nodulated, and so closely adapted to each other that a fine probe could be introduced between them with difficulty; there was no regurgitation. Pure aortic stenosis was rare, and it was generally considered the least serious of valvular lesions; but in this case it caused sudden death. The patient was not examined during life. In another specimen, removed from a man, aged fifty years, the heart was enormously enlarged, weighing 32 oz. (*cor bovinum*); both left

Digitized by Google

and right ventricles were hypertrophied and dilated and recent pericarditis was present, but all the valves were healthy.

Dr. MCWEENEY gave an account of a fatal case of Septico-Pyæmia associated with Acute Suppurative Arthritis in a boy, aged twelve years, after a slight blow on the right knee. The bacteriological examination revealed staphylococcus aureus in the fluid removed from the knee at the time of operation and also in the pericardial fluid, as well as in the foci in the lungs, myocardium, and kidneys. How it had obtained entrance was not clear. Dr. Mc Weeney also showed a preparation made from his own finger which had become infected at the necropsy without any wound, apparently along the shaft of a hair on the dorsal aspect of the second phalanx. In spite of active treatment a troublesome furuncle had resulted, the slough from which swarmed with the staphylococcus aureus. There was some lymphangitis, but he had fortunately escaped without glandular infection.

Dr. J. KNOTT exhibited 28 human ulnæ, showing united fractures in various positions, rachitic curves, arthritic deposits, and changes of various kinds.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—At a meeting on Thursday, Nov. 10th, the President, Dr. Alfred Robinson (Rotherham), being in the chair, Dr. Sorley showed a case of Lateral Sclerosis.—Mr. Lockwood gave particulars of a case of Foreign Body in the Cheek. The patient, a girl, aged twenty-nine years, was admitted into hospital with a suppurating sinus of the cheek. On examination under ether what was thought to be a piece of necrosed bone was found to be a piece of glass 2½ in. in length. It had perforated the malar bone and had passed through the antrum of Highmore along its orbital surface towards the posterior nares. The history was that twelve months previously the patient had fallen upon the fender and sustained a wound which had never healed.—Mr. Lockwood also showed a case of Myositis Ossificans Multiplex Progressiva and a Fœtus with Gastrochisis.—Mr. Herbert Hallam showed a case of Adeno-sarcoma commencing in the cervical glands seven years ago.—Mr. Connell showed (1) a patient who had been operated on for Purulent Peritonitis; (2) a specimen of Phagedæna of the Penis, and (3) microscopic slides of a case of Relapsing Appendicitis.—Dr. Burgess showed Two Children with Patent and Dilated Arterial Ducts.—Dr. Arthur Hall showed (1) a case of very large and numerous Gouty Tophi; (2) a case of Syphilitic Rosacea, and (3) a series of naked-eye and microscopical sections illustrating the Morbid Anatomy of Exophthalmic Goitre.—Mr. Godfrey Carter read a paper on the Etiology of Graves's Disease.—The discussion which followed was supported by the President, Mr. Archibald Cuff, Dr. Leonard Giles, Mr. Dale James, Mr. Garrard, Dr. Waddy, and Dr. G. Wilkinson.—At a meeting on Nov. 24th, the President being in the chair, Mr. Pye-Smith read a paper to introduce a discussion on Intestinal Obstruction with reference to Differential Diagnosis and Treatment. Commencing with a large and most markedly acute group when the bowel is strangulated by some internal band or other cause he insisted on the close similarity of such cases to cases of strangulated hernia and advocated equally prompt treatment by operation. The diagnosis and treatment of other acute and chronic groups were then discussed and the opinion was expressed that real differences in the symptoms are normally to be found between cases of intestinal obstruction owning widely different causes and that in spite of admitted difficulties the clinical problem may often be solved if there be a full, early, and correct history of the case, if a careful and thorough examination of the patients and an analysis of the symptoms be made, and if the probabilities suggested by age, sex, and statistics be allowed to have their full influence.—The President, Dr. Porter, Dr. Sinclair White, Dr. Gwynne, Dr. Kay, Mr. Archibald Cuff, Dr. Leonard Giles, Dr. G. Wilkinson, Dr. Burgess, and Mr. Keeling took part in the discussion.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—An ordinary meeting of this society was held at 20, Hanover-square, on Nov. 23rd, Dr. Radcliffe Crocker, the President, being in the chair.—The President showed (1) a little boy, five years old, suffering from Lichen Scrofulosorum Pilaris; (2) a female, aged twenty years, with Leucodermic Patches on the Neck; and (3) a case of Mixed Scleroderma in a male, aged nineteen years.—Dr. J. F. Payne showed a case of Acne Keloid (? sycosis frambæsiformis) in a man, aged about fifty years; the growth was on the scalp.—Dr. A. Eddowes showed a case of Persistent Erythema with Lichenoid Affection of the Limbs in a woman, aged about forty-five years. It was generally regarded as a case of atypical lichen planus.—Dr. Eddowes also showed a case of Typical Lichen Planus.—Mr. Campbell Williams read a paper on Congenital Syphilis: a New Theory.—Dr. A. J. Hall (Sheffield) read notes of a case of Eczema produced by Phenyl-hydrazin-hydrochlorate.—The papers and cases were discussed by the President, by Dr. J. F. Payne, Dr. Mouillot (Harrogate), Dr. A. Eddowes, Dr. Shaw-Mackenzie, Dr. Ogilvie, Dr. T. D. Savill, and Dr. A. J. Hall.

Reviews and Notices of Books.

A Text-book of Physiology. Edited by E. A. SCHÄFER, LL.D., F.R.S. Vol. I. Pp. xxiv. and 1036. Edinburgh and London: Young J. Pentland. 1898. Price 31*s.* 6*d.*

LESS than two years ago we reviewed in these columns an American Text-book of Physiology written by a number of the leading physiologists in the United States under the editorship of Dr. W. H. Howell. This was, we believe, the first text-book on the subject in the English language in which a number of physiologists collaborated. It has been speedily followed in this country by a similar treatise of even more monumental proportions. Not since the publication of Hermann's celebrated "Handbuch der Physiologie" has so comprehensive and important a work on the subject been attempted nor, we may add, crowned with such conspicuous success. Professor Schäfer has been fortunate in securing the services of many of the best-known physiologists in Great Britain as contributors to the text-book. This will be evident from a list of those writers who have combined to produce the present volume. Dr. Halliburton undertakes the opening chapters on the Chemical Constituents of the Body and of Food, and on the Chemistry of the different Tissues and Organs. The editor himself writes on the Blood and later on the Secretion of Milk, on Metabolism in general, and on Internal Secretions. Dr. Arthur Gamgee deals with Hæmoglobin and its immediate derivatives. Professor Waymouth Reid contributes chapters on the Processes of Diffusion, Osmosis, and Filtration, and on Secretion and Absorption by the Skin. Dr. Starling is responsible for the chapters on the Production and Absorption of Lymph and the Mechanism of the Secretion on Urine. Mr. B. Moore writes on the Chemistry of the Digestive Processes. Salivary Secretion is the subject of a monograph by Dr. Langley, while Dr. Edkins discusses the Mechanism of Secretion of the Gastric, Pancreatic, and Intestinal Juices and Dr. Noel Paton that of the Bile. The Chemistry of the Urine is the subject of Dr. F. Gowland Hopkins's contribution and the sections on the Chemistry of Respiration and on Animal Heat are by Dr. Pembrey.

It is not too much to say that each of these articles is a complete monograph, thorough, laborious, and lucid, written by a physiologist well known for his particular knowledge of his own subject. To attempt adequate criticism of them would need a special knowledge of each subject at least equal to that of their authors. There are few who possess such knowledge, but it is nevertheless possible to form a fair opinion of the value of the work by comparison with existing treatises and by persistent use as a work of reference whenever information is required on any special subject. The Text-book stands these tests not merely well, but in such a manner as to distance all competitors. It is not a book for the ordinary student—it is too comprehensive, too bewildering in its detail; some of the chapters are almost too encyclopædic. But to the physiologist, the pathologist, or the

Digitized by Google

physician in search of minute fact in support of any given opinion it will be found invaluable. Its main importance is, in fact, that of a comprehensive work of reference, sparing an enormous amount of trouble in the hunting up of original papers. It must remain for many years the standard work of reference on physiology in the English language, of value primarily to the physiologist but also to the worker in every branch of medical science.

Commercial Organic Analysis. By ALFRED H. ALLEN, F.I.C., F.C.S. Second edition, revised and enlarged. Volume IV. Proteids and Albuminous Principles. Proteoïds or Albuminoïds. London: J. & A. Churchill. 1898. Price 18*s*.

IN a review in THE LANCET of Oct. 3rd, 1896, of the third volume of this excellent book we remarked that when Mr. Allen's important work is finished he will have earned the gratitude of chemists, analysts, and others, for having added one of the most valuable books of reference on the subject with which it deals. The volume before us represents the end of the stupendous task which Mr. Allen undertook over fourteen years ago. It is the last volume of the second edition, the earlier volumes of which have been long out of print. We share in the author's regret that he finds it impossible to undertake the enormous labour of revising the earlier volumes, but a well-known authority on analytical practice has fortunately been found to continue this good work in the person of Dr. Henry Leffmann who has practically finished Volume I. and is now engaged upon Volume II. The time has come, therefore, when we can regard Mr. Allen's work as a whole, and we heartily congratulate him upon the result, and the chemical profession upon the possession of such a valuable and reliable source of reference on a very important and interesting branch of analysis. It is not difficult for the practising analyst to discover that the processes described throughout have in the majority of instances been tested in the laboratory by the author. Again and again he gives a review of the methods of analysis applied to a given substance and then relates his own experience as to the mode of procedure which he has found best and which introduces important modifications enabling the analyst to arrive more nearly at the truth. In proof of this the reader is constantly confronted with remarks in effect like the following (p. 294): "Numerous experiments made in the author's laboratory have shown the substantial accuracy of the process though various modifications were tried before this result was attained." The most interesting and valuable chapter in the present volume is, we venture to think, that dealing with Meat and Meat Products. Here we find all that is known up to the present time of the composition of meat preparations so far as analytical methods may be trusted. This portion of the subject obviously bears upon the comparative nutrient value of meat extracts, essences, &c., and a series of tables are included containing a great number of recent analyses in accordance with the results of improved methods, and the relative value of most of the commercial meat preparations on the market may thus to some extent be gauged. The subject, however, is still beset with difficulty owing to the want of physiological data as to the exact alimentary power of each constituent which analysis now identifies and separates. What, for instance, is the alimentary value of the gelatins, chondrin, gelatin-peptone, &c., and relatively of albumose and peptone? Until these questions are satisfactorily answered even the searching power of analysis to separate different constituents will avail little. In the same chapter is very properly contained a section on the Enzymes of the Gastric Juice with an excellent account of recent knowledge on the subject and a *résumé* of the methods of assaying pepsin. The method enjoined in the British Pharmacopœia of 1898 is described and in a footnote the author observes that "it is deplorable that those responsible for the production of the British Pharmacopœia should have adopted a process of pepsin-assay so unscientific in its principles and so defective in the details of its application." We are bound to admit the justice of this criticism. In the chapters dealing with the Analysis of Milk and Milk Products we again meet with evidence of the care which the author has taken to keep the history of all pertaining to the subject well up to the present time. We observe here for the first time in print a "Memorandum on the Analysis of Milk in the Government Laboratories." The author was favoured with an advance copy of this paper, which relates to the analysis of some milk by Dr. T. E. Thorpe, the principal of the Government laboratories. The process therein described seems complicated, and the simpler method first practised by Dr. Bell appears to give the same results according to Mr. Bannister, the late principal and deputy principal respectively at Somerset House. It is impossible that the analysis of sour milk can be as satisfactory as that of milk examined in the fresh state. On the question of food preservatives the author expresses no very pronounced opinion one way or the other, but refers to a footnote in which the opinions derived in response to our own inquiries upon the subject[1] from several medical authorites are conveniently epitomised. The volume concludes with 534 *addenda* which are short notes of reference to recent contributions bearing on the subjects treated in the body of the work. Amongst these references we observe a paragraph on the recent announcement of the alleged discovery of the synthesis of albumin. The author discredits the announcement as such but suggests that some fresh insight may have been gained into the composition and constitution of proteids.

"Allen's Commercial Organic Analysis" is undoubtedly a standard work upon the subject and the author must feel it no small reward for the great labour and deep thought which he has devoted to its preparation and completion that it is admitted to be the first work of its kind and one in which all those engaged in analytical work place confidence and trust.

The Sanitation of Domestic Buildings. By FRANK LATHAM, C.E. With Introduction by BALDWIN LATHAM, C.E. London: The Sanitary Publishing Company, Limited. 1898. Price 2*s*. 6*d*.

THIS little manual will be found most useful to all who desire an insight into the why and wherefore of the various pipes and appliances which ramify through, under, and about a modern dwelling. Having first dwelt upon the importance of efficient sanitary surroundings, Mr. Latham takes the sanitary work of the house in detail. Commencing with the drains he passes to the plumbing work and then considers the desirability or otherwise of the several internal fittings illustrated in the book. The work well exemplifies the best methods of the present day and the few trifling points upon which we may entertain any diversity of opinion are hardly worth discussion.

The author has endeavoured, so far as the subject will permit, to render it intelligible and useful to the uninitiated and with the aid of numerous illustrations has accomplished very much in this direction. Unfortunately for themselves and others the general reader and the householder are like Gallio who "cared for none of these things." We cannot deny a certain meed of sympathy to the general reader, for notwithstanding its vital importance the subject is both uninteresting and difficult and the general reader lacks the many years of industrious work and study which render the

[1] Vide THE LANCET, Jan. 2nd, 1897.

Digitized by Google

various details and technicalities so easy of comprehension to the expert. Mr. Latham need not despair, however, on this account, for there is much in his book of an educational character suitable to a large class of readers capable of assimilating its contents. These will find it full of information and particularly handy for reference.

The American Year-book of Medicine and Surgery for 1898. Edited by GEORGE M. GOULD, M.D. London: The Rebman Publishing Company. 1898. Pp. 1077. Price 38*s.*

THIS colossal work continues to maintain the high standard of usefulness which has hitherto distinguished it. Dr. Gould has the services of an editorial staff now numbering no less than 27 members, each of whom appears to be well qualified to deal with his own subject. Large as this staff is it cannot be considered excessive for the laborious task of abstracting a year's literature on medicine, surgery, and kindred subjects in every important modern language. The various articles are not merely abstracted, but in most cases a short criticism is appended representing the views of the member of the staff who deals with it, and this criticism is usually apt and to the point. A considerable number of figures and a few excellent coloured plates are introduced into the volume. The book is clearly and beautifully printed and no attempt has been made to diminish its bulk by the use of small type. Its size and weight are, indeed, by no means inconsiderable and constitute the only drawback which we can discover. Its value as a work of reference in every department of medicine and surgery is very great and is rendered greater by the thorough index which brings the volume to a close.

A Treatise on Human Anatomy. By Various Authors. Edited by HENRY MORRIS, M.A., M.B. Lond. Second Edition, revised and enlarged. London: J. & A. Churchill. 1898. Price 36*s.*

THE first edition of this work was published in 1893 and was reviewed in our issue of July 8th of that year. This, the second edition, differs only slightly from the preceding one, the difference mainly consisting in certain additional matter, such as the chapter on the Skin by Mr. William Anderson and one on Vestigial and Abnormal Structures by Dr. Arthur Robinson. Another useful addition is the table which appears on page 819 of the present edition dealing with the relations of the lumbar and sacral nerves to the branches of the lumbar and sacral plexuses and the relations of the muscles of the lower extremity to the nerves of those plexuses. We notice that the illustration of the very intricate dissection of the right side of the neck which appeared on page 1128 of the first edition has disappeared from the second, an omission which we cannot but think a wise one. Altogether the second edition is in many ways an improvement upon its predecessor, excellent though that was.

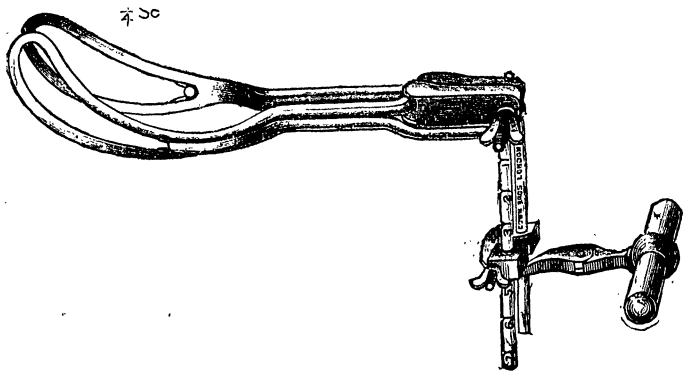
LIBRARY TABLE.

Radiation, an Elementary Treatise on Electro-Magnetic Radiation and on Roentgen and Cathode Rays. By H. H. FRANCIS HYNDMAN, B.Sc. Lond. With a Preface by Professor SILVANUS P. THOMPSON, D.Sc., F.R.S. London: Swan Sonnenschein and Co., Ltd., New York. The Macmillan Company. 1898. Price 6*s.*—The author in the opening sentence of his preface lends a beautiful emphasis to the scientific importance of radiation, for "it is owing to radiation that there is any life upon this globe and that man as a sentient being is able to appreciate the beauties of the world in which he lives." No wonder, then, that the pursuit of the study of radiation is fascinating. And this well-written volume deals with the results of such study as far as they have appeared up to the present time. The subject has of course received enormous stimulation by the discovery of the x rays. Since that announcement other radiations ordinarily invisible to the eye have been discovered. The book is divided into three parts, Part I. dealing with material vibrations, Part II. with ethereal vibrations, and Part III. with other forms of radiation, as the x rays and so on. The book is obviously intended for the student who possesses a fair knowledge of physics. It is not popularly written and Professor Thompson says that it is much too good to be of use to one whose highest aim is to pass examinations. In a word, it is an excellent scientific dissertation, giving a clear, precise history of the development of the subject and of its trend in relation to the results of recent researches.

The Discharge of Electricity through Gases. By J. J. THOMPSON, D.Sc., F.R.S. Westminster: Archibald Constable and Co. 1898. Price 4*s.* 6*d.*—This little work had its origin in a course of four lectures on Discharge of Electricity through Gases which were delivered at the University of Princeton, New Jersey, by Professor Thompson in 1896. New matter has necessarily been added, since this field of study has recently attracted a large number of investigators. The chapters contain an account of a very interesting number of electrical phenomena connected with the discharge of electricity through gases, as in the production of photo-electric rays and of cathode rays. It is remarkable what an enormous subject has been opened up by the manifestations observed on the discharge of electricity through gas at different densities. The experiments first conducted by Sir William Crookes on radiant matter, when he dealt with the electric discharge through highly attenuated gases, must be regarded as largely the origin of so much fruitful work in the study of this branch of research. Professor J. J. Thompson is an ardent investigator in this field and an admitted exponent of the subject, so that the publication of his views will be welcomed by those pursuing this interesting line of inquiry.

From Messrs. Raphael Tuck and Sons we have received their usual Album of Christmas and New Year's Greeting Cards, together with several specimens of artistic productions of a more pretentious character. Among the cards those of the "Japanesque," the "Celluloid hand-painted," and the "Marble" series call for special mention. A design which will also doubtless attract much attention is that of "The Holy Child," depicting the Babe recumbent in His cradle, under a canopy, with adoring angels in the background, the whole being constructed to open out in elliptical form and presenting an excellent picture. In platino panels of various sizes there are several examples of really good work, and Turner's Masterpieces will appeal to many. The whole of Messrs. Tuck's productions are deservedly popular for excellence of design and for effective and at the same time artistic carrying out.

JOURNALS AND REVIEWS.



In the *Cornhill Magazine* for December the Rev. W. H. Fitchett continues his series of "Fights for the Flag." The fight in this paper, however, was not won on an ordinary battle-field where there is the lust of battle to excite the combatant, but in the horrors of the great hospital at Scutari, and the protagonist was no grim warrior but the gentle "lady with the lamp," known to all the world as Florence Nightingale. No words are needed from us to praise her and her devoted companions, but what the British army, nay, every army, owes to them may be seen by comparing military nursing before their advent with the nursing of our troops in the Soudan.

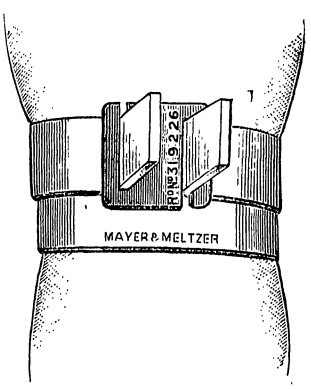
New Inventions.

AN IMPROVED FORM OF AXIS-TRACTION MIDWIFERY FORCEPS.

THESE forceps are the result of twelve months' experiments. They have been used in from fifty to sixty forceps deliveries in normal and abnormal pelves, the position of the head varying from "above the brim" to "on the perineum." They have given every satisfaction to those who have used them. They are made entirely of metal and can be sterilised by boiling. The traction rods are detachable and easily cleaned. The weight, especially where undesirable, has been diminished as much as is consistent with perfect

rigidity, the diminution being most marked in the application handles, the latter thereby acting the more efficiently as true indicators of the change in the direction of the descending head. There are no screws or fixed joints excepting in those parts outside the vulva, and such screws as are present are few in number and not easily lost. When the head is delivered it is only necessary (without touching the traction apparatus) to give a few turns to the large screw on the handles, when the blades slip off the head.

The blades have a pelvic curve of a 7 in. radius. This enables a good grasp to be obtained on the correct plane of the head. The cephalic curve, too, is more abrupt than usual. The blades are rigid, enabling the operator to judge to a nicety the force being used; they are also less likely to cut the head. They are stout, but narrower than ordinary blades, rendering them easy of introduction and manipulation and of special service in those difficult cases of flattened pelvis when the head lies transversely at the brim. By being narrow they grasp only the occipital and frontal bones, avoiding the parietals and so enabling the latter to mould without hindrance in the diameter of greatest obstruction. This has been verified by delivering a stillborn child through a dummy pelvis artificially flattened. The lock is a close-fitting ordinary English lock; a model has also been made with reversed lock. The close-fitting lock ensures the blades when locked being properly adapted to the head. The application handles have been much shortened and lightened; once the blades are applied the handles are merely "indicators" and not designed for traction. Owing to their lightness they do not fall towards the lower thigh and the slightest movement of the head is communicated to them. Being so delicate a guide, to ensure proper axis traction throughout the operator has merely to pull, keeping the traction rods constantly parallel to and close to the application handles as the latter move forward with descent. Another great advantage of the short handles is that on locking the forceps the second traction rod falls into position without having to be carried far forward to clear a long application handle. A theoretical objection that the short handle would upset the balance of the blade, and make it difficult of introduction with the head high up, has been found to be purely theoretical even above the brim, for in introduction the traction rod and handle are grasped together and will be found to give a comfortable and convenient hold, the left blade being passed with its traction rod behind the handle, the right blade with its rod just in front of the handle. On locking the second traction rod slips backwards into position beside the first traction rod. The traction rods are the well-known rectangular ones of Dr. Milne Murray (used by his kind permission). The forceps are thus true for all pelves instead of being true only for a normal pelvis. By an ingenious contrivance, copied from Dr. Cullingworth's forceps, the rods are easily detachable by an aseptic joint, the old objectionable screws being done away with.



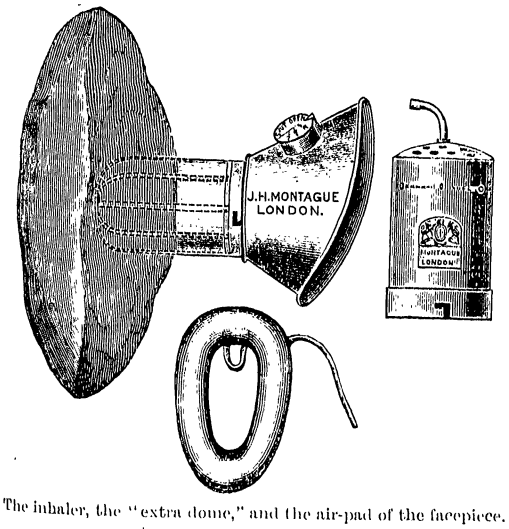
Much time and care have been expended by Messrs. Down Bros. of 21, St. Thomas's-street, S.E., in designing a new form of traction block which should be mathematically and mechanically correct and yet have the advantage of simplicity, lightness, ease and rapidity of application, and admit of being easily cleansed. The great difficulty has been to avoid screws which might be lost and make the instrument temporarily useless. I venture to think that the present block fulfils the necessary conditions. To ensure asepsis it can be boiled. One movement fixes the block and rods securely. The line of traction has been calculated by "shadow projection," the ray of light being kept perpendicular to the blade. Very accurate results are obtained by these means.

In conclusion, I must thank Dr. Milne Murray for many valuable suggestions and Messrs. Down Bros. for their care and attention to the mechanical details, which are of the utmost practical importance in ensuring success.

G. PORTER MATHEW, M.D. Cantab.

A NEW PATTERN OF TOURNIQUET.

VARIOUS forms of tourniquet are in use at the present day. Petit's tourniquet is still sometimes employed, but it has been in great part replaced by Esmarch's rubber tube. The tube is very useful but has several disadvantages, due probably to the constricting force being applied over a very small area. A more effective method has been adopted in a tourniquet just sent to us by Messrs. Mayer and Meltzer of 71, Great Portland-street. The tourniquet consists of two parts—a flat indiarubber band and a steel fastener. The advantage of the band over the rubber tube lies in the fact that it apparently does not constrict the deep tissues to the same extent, and it does not cause any abrasion of the skin. The band in Messrs. Mayer and Meltzer's



instrument is 31 in. long, 1 in. wide, and $\frac{1}{16}$ in. thick. The fastener consists merely of a thin metal plate 2 in. square, having two parallel slots 1¼ in. long, cut into opposite edges. One end of the band having been stretched a little is passed into one of the slots and firmly held there by its own expansion, the free end is wound tightly twice round the limb and similarly fixed in the other slot. The whole instrument is very simple and cannot get out of order. It can be quickly applied and removed and does not allow any slip.

IMPROVED ORMSBY INHALER WITH ATTACHMENTS FOR THE ADMINISTRATION OF THE A.C.E. MIXTURE OR CHLOROFORM.

HAVING used Ormsby's inhaler almost entirely during the last ten years for the administration of ether I have become fully convinced of its many good points and also acquainted with its few defects. The principal defects are (1) the smallness of the air-valve; (2) the cage being composed of galvanised netting is compressible and so becomes more and more conical with use and hence obstructed, allowing less and less room for the sponge; and (3) it cannot be thoroughly cleansed with facility. With the object of overcoming these defects I have had the inhaler constructed as depicted in the woodcut and have been using it entirely for over twelve months with gratifying results. It is constructed throughout of metal nickel-plated, all parts are easily accessible, there is no place where saliva, mucus, or blood can lodge, and it can be rendered aseptic by boiling if necessary. The air-valve is a free one and is numbered with figures, as on Clover's inhaler, so that at a glance the relative patency of the valve can be seen. In passing, I may mention that it is my practice upon the addition of ether to the sponge to throw the valve wide open and then to gradually diminish the opening to three-quarters, one-half, one-quarter, and shut, thereby greatly reducing any chance of coughing or interfering with the rhythm of respiration when the fresh vapour is inhaled. In certain cases the valve can be kept at one-quarter throughout the administration with benefit. The cage being rigid and of very open work is incompressible, permits of free respiration, and cannot gradually become constricted with use. The respiratory bag is 12 in. in diameter, so that there is no need of netting to prevent its being blown off during expiration—the majority of bags sold with inhalers are much too small. The cage bearing the sponge and respiratory bag fixes on the facepiece with a bayonet catch, and is instantly detachable for cleansing purposes. An extra dome has been constructed of metal and freely perforated with air-holes, at its extremity, likewise fitting on to the facepiece with a bayonet catch and taking the place of the other dome. I have found this attachment very useful for the administration of the A.C.E. mixture or for ether when plenty of fresh air is necessary, as with young children and the very feeble. The administration can be begun with the A.C.E. mixture, and then the A.C.E. dome detached when required, the other dome applied in its place and the administration continued with ether; this method I have found very convenient. Should it be desirable to change the anæsthetic to chloroform, the tube from a Junker's inhaler can be applied to the projecting tube of the A.C.E. dome, and the chloroform apparatus is thus complete. Should the entry of air be too free then some of the holes at the extremity of the dome can be occluded with the hand—a good plan as the respirations can be felt—or these holes can be in part occluded by packing cottonwool in the dome beyond the retaining spikes intended for that purpose, care being taken not to plug the opening through which chloroform vapour is injected. With this inhaler, ether, the A.C.E. mixture, or chloroform can be administered either throughout or in succession, so that it is more or less of a universal type. In point of weight and initial expense it contrasts unfavourably with the Ormsby inhaler, but with the air-pad and bag occasionally renewed it is practically indestructible and will last a lifetime. I am indebted to Mr. J. H. Montague, of 101, New Bond-street, W., for the great pains he has taken in the construction of this inhaler.

The inhaler, the "extra dome," and the air-pad of the facepiece.

Wimpole-street, W. C. CARTER BRAINE, F.R.C.S. Eng.

Analytical Records FROM THE LANCET LABORATORY.

PURE MUTTON ESSENCE (HIPI BRAND).

(G. NELSON, DALE AND CO., LTD., 14, DOWGATE-HILL, E.C.)

ON examination this preparation proved to be a firm extract presenting the following proximate composition: moisture, 35·20 per cent.; organic matter, 56·38 per cent.; mineral matter, 8·42 per cent. According to our analysis the composition of the organic matters was as follows: total proteids, 38·22 per cent.; meat bases, 16·60 per cent.; fat, 1·56 per cent. The proteid matters insoluble in cold water amounted to 7·72 per cent., while the proteid matter thrown down on boiling and after the addition of a few drops of acetic acid was 1·21 per cent. It is well known that mutton is more digestible than beef on account of its fibre being smaller and more tender, but on the other hand the fat of mutton is harder and probably less digestible. Moreover, the proportion of fat in mutton is very often considerable. Practically all this fat, however, is separated during the preparation of the extract, the residue only amounting, as will be seen from our analysis, to 1·56 per cent. The composition of this extract, judging by the above analysis, establishes its nutrient value. Indeed, the ratio of nutritive substances to mere stimulating principles is very satisfactory. Further, the flavour is good. The preparation compares, from the dietetic point of view, very favourably with similar beef derivatives.

GUADRAC (SPANISH RED WINE).

(THE ALASCO WINE CO., 3, LINCOLN'S-INN-FIELDS, W.C.)

In spite of the low price (12s. per dozen) we believe this wine to be genuine. It was in sound condition, delicately fruity to the taste, free from excessive acidity, and containing only a minimum of sugar. Our analysis was as follows: total extractives, 2·35 per cent.; mineral matter, 0·23 per cent.; sugar, 0·67 per cent.; fixed acids calculated as tartaric acid, 0·49 per cent.; volatile acids calculated as acetic acid, 0·06 per cent.; alcohol, by weight 11·62 per cent., by volume 14·37 per cent., equal to proof spirit 25·18 per cent. The wine is pure, of a desirably light character, and therefore well suited for table purposes.

SULPHAQUA.

(THE SELTZOGENE PATENT CHARGES CO., ST. HELENS, LANCASHIRE.)

The packets for the production of "sulphaqua" are two in number, each consisting of a well-known salt the precise nature of which our analysis has determined. Both are soluble in water, and when the resulting solutions are mixed a double decomposition takes place, a yellowish opalescence forms which gradually intensifies into a very finely divided precipitate of sulphur, while at the same time a smell of sulphurous acid is evolved. For the purposes of a bath the mixture is thrown into from 10 to 20 gallons of warm water. This idea deserves the attention of all those interested in the application of sulphur in the treatment of affections of the skin or in

Digitized by Google

gout and rheumatism, since by this method the sulphur should be in a very active condition—a condition, if sulphur is valuable at all, which should insure therapeutic effect. Indeed, the nature of the reaction is such as to produce partly a colloidal form of sulphur which appears to be soluble in water. The same thing occurs when sulphuretted hydrogen is passed through a solution of sulphurous acid. Sulphur charges are prepared suitable for use in the bath or of a smaller size for use in the washhand-basin. The bath prepared in this way is distinctly pleasant, culminating in a healthy reaction. The idea, we think, is well worth applying as a new and probably valuable recourse in balneological practice.

EUGOL TOOTH POWDER.

(BAYARD, SONS, AND BAYARD, LIMITED, NEW YORK, AND 26, BRIDLE-LANE, GOLDEN-SQUARE, W.)

The statements advanced in favour of this preparation are true according to the composition which our analysis assigns to it. Thus it contains agreeable ingredients, rendering it antacid, antiseptic, and mildly astringent, the latter property making it useful for hardening the gums. It is a smooth powder free from grit having an agreeable smell of a well-known antiseptic volatile oil. The absorbent is calcium carbonate in a finely comminuted form. This dentifrice is pleasant to use, imparting an agreeable sense of cleanliness to the mouth.

SCOTCH WHISKY.

(F. BAGGER, 3-4, GT. WINCHESTER-STREET, E.C.)

Smooth to the taste, somewhat light in colour, and of satisfactory alcoholic strength are the main features of this spirit according to our examination and analysis. It has the character of a spirit which has been matured, it contains a very small percentage of extractives, and it is practically free from saccharine matters. The analysis was as follows: alcohol, by weight 39·30 per cent., by volume 46·59 per cent., equal to proof spirit 81·64 per cent.; extractives, 0·23 per cent.; mineral matter, 0·02 per cent.; acidity reckoned as acetic acid, 0·039 per cent. From the last factor it will be seen that the whisky is practically neutral. These results indicate the genuineness of the spirit, which is therefore well adapted for dietetic purposes.

RHENS NATURAL MINERAL WATER.

(RUSTON AND SINCLAIR, 3, CROSS-LANE, ST. MARY-AT-HILL, E.C.)

Our analysis of this interesting water drawn from a spring on the banks of the Rhine is not appreciably different from that already published. Thus the total saline constituents amounted to 3·48 grammes per litre. The alkalinity was equal to 1·33 grammes of carbonate of soda, the common salt was found to be 1·34 grammes per litre, while the sulphate of soda amounted to 0·81 gramme per litre. The last item is a feature distinguishing this water from some other natural waters. On this account it probably acts very mildly as an aperient. It is satisfactorily charged with carbonic acid gas, is pleasant to the taste, and contains a distinct trace of lithium. It possesses the characters of a water containing no added ingredients either saline or gaseous and it clearly belongs to the alkaline carbonate class of waters which are useful in promoting a sedative action.

(1) BELLADONNA PLASTERS; AND (2) ASEPTIC LIGATURES.

(SEABURY AND JOHNSON, NEW YORK, AND FASSETT AND JOHNSON, 31 AND 32, SNOW-HILL, E.C.)

We have received specimens of belladonna plasters from the above firm which are not only satisfactory on account of the excellence of the rubber basis but—of more importance still — are standardised in regard to the constituents of belladonna, the yield of alkaloids on analysis being just slightly over ½ per cent. An interesting inquiry was undertaken in this connexion not very long ago, when it was found that of several plasters examined some contained no alkaloid, one of these being labeled "Poison." The British Pharmacopœia now requires 0·5 per cent. of the alkaloids of belladonna root in the plaster. It is obviously important that the belladonna plaster should be a standard preparation and proceedings can be instituted under the Food and Drugs Act if the preparations contain no alkaloid or are defective in strength. Messrs. Seabury and Johnson claim to have always provided a plaster yielding on analysis ½ per cent. of the belladonna alkaloids. However that may be, the specimens submitted to us, which were said to be taken at random out of a stock, gave a full and satisfactory yield of alkaloids in accordance with pharmacopœial requirements. These plasters, therefore, may be relied upon. We have also received a few specimens of aseptic ligatures. They are enclosed in tight capsules. The closed capsule is sterilised together with the ligature it contains. This method secures an aseptic cord, but of course the capsule should be opened under as strictly aseptic conditions as possible.

(1) CREOSOTAL; (2) DUOTAL; AND (3) HEROIN.

(THE ELBERFELD FARBEN FABRIKEN CO., LTD. LONDON AGENCY: 19, ST. DUNSTAN'S-HILL, E.C.)

These three comparatively new and interesting preparations call for notice. The first two are fairly well known as having been administered in the treatment of tuberculosis, the basis of the compounds being respectively creosote and guaiacol. Creosotal may be regarded as carbonate of creosote, but in reality it is a mixture of the phenol carbonates of creosote. It is a clear yellow, oily liquid with a slightly bitter taste but without odour, this latter property of course distinguishing it from pure creosote, and it has been administered in doses of from half a drachm increasing to five drachms in wine, brandy, or cod-liver oil. Duotal, on the other hand, is a white crystalline powder without taste or smell and is insoluble in water. It is the carbonate of guaiacol. It splits up in the alimentary canal into guaiacol and carbonic acid and is said to produce an increase of appetite and a favourable effect on nutrition whilst reducing the pathological conditions characteristic of phthisis. Heroïn is a morphine derivative, the "di-acetic ester." It is a white crystalline powder soluble in spirit but insoluble in water. It is said to be a favourable substitute for morphine by not altering the blood-pressure and thus to be well borne by persons of a weak heart and feeble arterial system. Heroïn is also said to be free from other disagreeable secondary effects of morphine, so that it may be administered in respiratory diseases and in phthisis in comparatively large doses with no effect but that of a sedative upon the air passages. These statements are so promising as to render desirable a careful clinical trial of this new derivative in this country.

WHITE'S ANGOSTURA BITTERS.

(MR. M. BETHENCOURT, CURAÇAO, WEST INDIES. EUROPEAN AGENT: MR. R. L. LEYBA, 16, GLOCKENGIESSER WALL, HAMBURG.)

On analysis this proved to be a very powerful spirituous extract of angostura bark (cusparia cortex). It is perfectly miscible with water, the solution developing a peculiarly pleasant aromatic smell. Angostura bark appears to contain two alkaloids—cusparine and galipine—which are possibly the active ingredients which make the bark of value in intermittent fever, dysentery, &c. The bitter principles are of the nature of a glucoside, since on boiling the above preparation with sulphuric acid a sugar-like substance was produced which reduced Fehling's solution. The preparation before us possesses a fine aromatic and bitter flavour and in proper quantity is well known to serve as an excellent and wholesome stomachic and tonic.

THE LANCET.

LONDON: SATURDAY, DECEMBER 3, 1898.

OUR anticipation that the meeting of the General Medical Council would be a prolonged one has been fulfilled. The Council sat for nine days, and, even so, had to leave many items on the programme for consideration at the May meeting of next year. The penal cases occupied a large part of four days, and the lessons of them and of the way in which the Council dealt with them may perhaps engage our attention on a future occasion. Meantime it is not uninteresting to notice the discussion on the subject of the Penal Cases Committee. It is evident that the disciplinary function of the General Medical Council figures as largely in the eye of the medical profession as its educational work. It is not only that the qualifying bodies show a constantly increasing disposition to impose on the Council the burden of investigating and punishing medical misconduct, but that the general body of the profession, and even the public itself, look to the Council for the correction and punishment of such misconduct. If the qualifying bodies, and especially the universities, give their sanction to the proposals which the Council is making to the Government—to the effect that practitioners whose names have been taken off the Register, either after conviction in a court of law or for "infamous conduct in a professional respect," should be deprived of their degrees or diplomas for so long as their names are off the Register—they will do much to increase the importance of this function of the Council. Accordingly, it is not to be wondered at that everything concerning the Penal Cases Committee, the body which assists the President in considering cases which seem to call for the discipline of the Council, should be narrowly criticised. Its constitution, the mode and time of its election, and the number of its members have all been from time to time—and notably at the recent meeting and at the instance of Mr. HORSLEY—subjects of discussion. Mr. BROWN made a bold attempt to abolish the committee altogether and to refer all penal cases to the consideration of the Branch Council of the division of the kingdom in which they occur, with a view to their presentation to the General Medical Council. His main argument was that the Penal Cases Committee had not in all cases done its work well, and that such work would be better done by the Branch Councils. Other members in support of this view argued that the Penal Cases Committee was too small and too strictly limited to London members, and that the Branch Council of England was too little *en évidence* considering its great responsibilities and its great wealth. But only 6 votes were given for Mr. BROWN'S proposal. The cost of meetings of the Branch Council was one thing which weighed against the success of the motion. The recent case of EASTBURN, in Scotland, which to medical minds seems a most easy one, shows that a case may be prepared and put forward by a Branch Council and yet fail to carry the judgment of the court of law. One change, however, has been made in regard to this important committee which has the duty of preparing cases of alleged professional misconduct for the consideration of the Council. The Council has determined that it shall be subject to election annually, like all the other committees of the Council. It will be elected in May by ballot, as the Executive Committee of the Council is elected. Hitherto it alone of all the committees has had a continuous existence and it was argued that there were special reasons for such continuity. But this point may safely be left to the judgment of the Council, which shows no harsh disposition to depose its members from any committee unless they have failed to do their duty. The suggestions of the minor changes in the Standing Order of the Council with reference to the functions and election of the Penal Cases Committee are mainly to be credited to the initiation of Mr. HORSLEY.

The chief occupation of the Council on the days when it was not engaged in the consideration of penal cases was the discussion of the report of the Education Committee on the important subject of the examinations in preliminary education recognised by the Council. Some educational experts in and out of the profession, who will entirely approve of the action of the Council in removing from its list the examinations for a second-class certificate (of first or second division) of the College of Preceptors, will regret that it did not go further. But it was scarcely free to do so, even if it had felt justified. The Council by its own resolution at a previous meeting had committed itself to remove all examinations which were of a lower standard than that of the junior local examinations of Oxford and Cambridge, thus constituting these a test standard of efficiency. The able and elaborate inquiries of the Education Committee, the credit of which, according to its chairman, is largely due to Dr. DONALD MACALISTER, left no doubt that this particular examination of the College of Preceptors is inferior to the junior local examinations. At least, the consensus of head-masters on this point is almost complete, and the great majority of deficiencies in general education reported in the examinations for navy and army medical appointments are traced to this examination. It may be taken for granted, therefore, that in the step it has taken the Council will have the decided approval of all who believe that the best foundation for a good professional education is a sound general one. Many members of the Council and many more outside think, as we have said, that the Council should have proceeded to remove all the junior examinations from their list. Theoretically the whole Council seemed to approve of such a step. But the cautious members succeeded in postponing the taking of it for a time. Rightly or wrongly, the impression prevailed that it could not be taken with due consideration for teachers or the parents of students, and that, further, it was impracticable with reference to the supply of the profession. One speaker after another agreed that the schools would be depleted and that the public and the public services might be seriously starved,

Digitized by Google

especially in the event of a great war, for the want of medical students and practitioners. We confess to few fears on this subject and to thinking that the profession is already so full that it could experience nothing but advantage and improvement from a much sharper rise in the standard of preliminary education than the Council has effected by its cautious action on Tuesday. But it is satisfactory to know that it has virtually committed itself to a further raising of the standard by calling on its Education Committee to say in May next when such a step may be safely taken. We trust that the Education Committee will display as much energy and efficiency in answering this question as in establishing the relative superiority of the university local examinations.

The only other important action of the Council which we need notice here is the adoption of the report of its Committee on the Midwives Bill. The discussion turned merely on details and especially on the importance of provisions for securing that the Council shall be indemnified for the cost of discharging any duties which may be imposed on it under any such Bill. There was no attempt in any quarter to revert to the general principles of such measures. On these the Council has practically said its last word. It proceeded, however, very wisely to reappoint its last committee with the addition of Mr. HORSLEY'S name to watch any actual measure which may be brought forward in the coming session.

ALL who were present at the recent meeting of the Fellows and Members of the Royal College of Surgeons of England must have been struck by the unusual air of urbanity which seemed to pervade the theatre, and, indeed, it was referred to by several of the speakers. It is a happy augury for the future, and we can only hope that those who take part in the meetings at the College will recognise that in College politics there is room for two reasonable opinions. The meeting was opened as usual by a short address by the President in which he referred to the chief events in the past Collegiate year. He showed that the Council had taken an important part in obtaining from the Government the reforms in the Army Medical Service resulting in the establishment of the Royal Army Medical Corps. Further, he pointed out that when an attempt was made last year by the authorities in Italy to require that the British medical men practising in Italy should be compelled, not only to take an Italian degree, but to go through the whole curriculum from the very beginning as if they were completely unqualified, the representations made by the Council to the Secretary for Foreign Affairs had the effect of eliciting from the Italian Government a statement that no change in the law was intended. The President also referred to the action taken by the Council with regard to the Midwives Bill, which they opposed, as it did not offer an adequate solution of the question of the registration of midwives. He also mentioned the great amount of work which was done in the Laboratories of the Conjoint Board on the Victoria-embankment, under Dr. SIMS WOODHEAD, especially alluding to the preparation of diphtheria antitoxic serum. This latter had, he said, been possible chiefly through the munificence of the Goldsmiths' Company's grant, and he expressed a hope that that company would see its way to make a further grant for the same purpose. In various other ways the President showed that the Council had been far from idle during the past year.

He had also to ask for the sympathy of the meeting. The claim of the College for exemption from corporation duty had practically failed and after careful consideration the Council had decided to appeal against this decision. Thus far nothing which had been said could have been objected to by any Member present, but one or two of the resolutions brought forward later displayed a little antagonism to the Council, yet neither the words of the resolutions nor the speeches of those who supported them showed anything of the bitter opposition which formerly characterised these annual meetings. The first resolution, introduced by Mr. GEORGE BROWN, congratulated the members of the Council on the success which had attended their efforts in the reform of the Army Medical Service, and invited them to turn their attention to the abuses existing in connexion with civil medical practice. Abuses there are without doubt, but it is not always clear how they may be remedied. The suggestion made by Dr. DANFORD THOMAS, who seconded the resolution, that an attempt should be made to obtain a new Medical Act was one of great value. As he pointed out, the present Act was inadequate and uncertain and was constantly being interpreted by magistrates and judges in different ways. Dr. DANFORD THOMAS said that the support of the Council was necessary and would of itself render almost certain the success of the measure. We regard this suggestion as well worthy of attention, though we are not so sanguine as Dr. DANFORD THOMAS as to the immediate result. It would, however, be a great step forward if this Council would coöperate heartily with the rank and file of the College in an endeavour to remedy present abuses.

When the Council some time ago claimed in rather enigmatic phrases to represent all the Members as well as all the Fellows it was obvious that such a claim would on many occasions be disputed, and therefore no surprise was felt on seeing it called in question in the second resolution. We have written so recently in favour of the reasonableness of the extension of the franchise to the Members that it is unnecessary here to say more than that the arguments brought forward by Mr. HUTCHINSON two years ago were quoted extensively by the mover of the resolution. Many Members supported it, and a Fellow—Mr. BELL of Rochester—suggested that if the Council were to obtain powers enabling them to coöpt Members to seats on the Council they would find them as good business men as the Fellows, and then there would be little opposition on the part of the Council to giving votes to Members. No dissentient vote was recorded when the motion was put to the meeting, and we hope that before long this ordinary act of justice will be performed. Mr. W. G. DICKINSON'S motion asked the Council to express its disapproval of Fellows or Members of the College acting as the paid officials of any association which advertises or touts for patients. He stated that the Royal College of Surgeons in Ireland had prevented its Members from holding such posts and he asked why the English College could not act in the same manner.

Digitized by Google

Mr. STOCKER mentioned that he had brought before the Council a flagrant instance of advertising by a Member of the College and yet the Council had taken no notice; but Sir WILLIAM MAC CORMAC rose and stated that he was sure that Mr. STOCKER would learn with pleasure that the name of the Member in question had been removed from the roll of the College. This was a distinct score for the Council, and this opportune announcement was received with much applause by the meeting. The President, continuing, said that the Council had on many occasions considered with much care the difficult question of these advertising associations, but their powers were very limited and they could not go beyond them.

Many Fellows have accepted with pleasure the permission accorded to them by the Council to wear an academical gown, and it is only natural that Members should wish to have a like privilege accorded to them. The seconder of a motion to this effect attempted to give reasons why Members should be allowed to wear a gown, and so far as we could gather from his remarks he thought that it would look better in an operation if the operator and his assistants were clothed in flowing white garments with a purple hem instead of in the mackintosh aprons which are usually worn. He explained, to the great amusement of the meeting, that a higher character would be given to the operation under these circumstances and that the sight of the surgeon and his assistants would have a soothing effect on the patient if he were to become conscious before the conclusion of the operation. Although one Member opposed it, the resolution was carried. Two other motions were on the agenda paper in the name of Mr. R. B. ANDERSON, but as he did not attend they fell to the ground We are sure that Mr. ANDERSON'S intentions in putting down these motions on the paper were good, but we fear that their involved verbiage would have done much to imperil them if they had come to a vote and we advise him to use shorter sentences and simpler phrases if he would be "understanded of the people."

Altogether we consider the meeting the most satisfactory of any held at the College within recent years.

THE subject of tuberculosis, with respect both to its causes and its prevention, is one which now happily attracts an increasing degree of interest not only in our own profession but among the public generally. It is greatly to be desired that this interest shall not be allowed to flag, for in spite of the great reduction which has recently been observed in the ravages of tuberculosis, this malady, in one or other of its forms, still continues to inflict upon the community an appalling amount of sickness and suffering which frequently ends in untimely death and very much of which is now definitely known to be avoidable. Since the year 1894 two Royal Commissions have reported upon different aspects of this subject; and quite recently a large and representative association,[1] headed by the President of the Royal College of Physicians of London and the President of the Royal College of Surgeons of England, has been founded in London, with coöperating branches in the provinces, having for its object the study of tuberculosis in man as well as in the animals which provide him with food. This association, which fully deserves its assumed title of "National," is seeking to discover some practicable means of still further diminishing, if not altogether exterminating from amongst us, the terrible scourge of tuberculosis.

Under these circumstances we recognise a singular appropriateness in Sir RICHARD THORNE'S selection of the present time for the delivery of his Harben Lectures on the Administrative Control of Tuberculosis. Having studied them carefully since their completion we have formed the opinion not only that these lectures are admirably adapted to the important occasion which called them forth but that they are in every respect worthy of Sir RICHARD THORNE himself.

The Harben Lectures of 1898, three in number, full abstracts of which have appeared in recent issues of THE LANCET, possess exceptional value for those who desire reliable information on this question, inasmuch as they furnish an authoritative statement from one whose position as medical adviser to the Government gives him the best title to be heard, not only as to the amount of mischief which actually accrues from the ravages of tuberculosis but also as to the degree of success which may reasonably be looked for as the result of such preventive action as is now practicable or of such measures as are likely to be sanctioned by Parliament for the control of tuberculous disease not only among mankind but among the lower animals likewise.

Up to a comparatively recent period our national records concerning mortality from tuberculosis appear to have been obscure, but the statistical investigations which Dr. TATHAM conducted in 1896 for the guidance of the last Royal Commission on Tuberculosis provide as trustworthy a summary of such information on this subject as can legitimately be deduced from the records in the General Register Office. Concerning the early history of tuberculous disease in this country the data obtainable from the death registers are less precise than we could wish. Previously to 1837, in which year the first Registration Act was passed, no official records of a reliable character were available, and for several years subsequently the existing records are too indefinite for comparison with those of more recent times. In those early days not only was attestation of the cause of the deaths of their patients entirely optional on the part of medical practitioners, but the names by which many of the diseases were at that time known now appear to us vague and ambiguous. Added to which, in consequence of the imperfect state of medical knowledge, it is certain that diseases were less accurately diagnosed in the "thirties" and "forties" than they are at the present time. For these reasons amongst others Sir RICHARD THORNE adopts Dr. TATHAM'S limitation—namely, the year 1851—as the earliest period the records of which concerning tuberculous mortality ought to be employed for purposes of comparison.

The period of forty-five years ending with 1895 has been marked by a reduction of almost 40 per cent. in the aggregate mortality of tuberculous diseases. The reduction has been remarkably steady and continuous throughout that period,

[1] The National Association for the Prevention of Consumption and other forms of Tuberculosis. Offices: 20, Hanover-square, West.

Digitized by Google

and has affected all the age-periods of both sexes into which the span of life is divided in the official tables; and what is especially encouraging is the fact that the chief part of the life-saving represented by this fall in the death-rate has been experienced at those age-periods when human life is economically the most valuable—namely, during adolescence and early maturity. In the mortality due to pulmonary phthisis, the most important member of this group, there has been since the decade ending with 1860 even greater reduction than in that resulting from tuberculous diseases generally; a fall has taken place in the death-rate at every stage of life, and in the several age groups comprised within the interval between the fifteenth and forty-fifth years the fall since that decade has ranged from 32 to not less than 58 per cent.

Among children of very tender years pulmonary phthisis is seldom fatal nowadays and among infants under five years old such mortality as still occurs averages only one-third of what it was forty-five years ago. But there is one member of the tuberculous group, tabes mesenterica, to which children are especially liable, and the mortality from this malady instead of falling has actually increased since 1860 by nearly 28 per cent. The question naturally suggests itself, why this particular form of tuberculous disease should still continue to increase very seriously amongst children whilst pulmonary phthisis, which is another form of the same group and is caused by the same parasite, is as steadily decreasing. Sir RICHARD THORNE is prepared with an explanation, which appears to us a reasonable one, of this apparent anomaly. He shows that whereas pulmonary phthisis is perhaps ordinarily caused by the inhalation into the lungs or air-passages of the dried and pulverised sputa of persons already suffering from that disease tabes mesenterica is mainly caused by the ingestion of food, especially of uncooked milk from diseased cows, which contains the tubercle bacillus in an actively infective state, the latter finding its way into the glands of the mesentery by way of the digestive tract. This theory at any rate explains the differing behaviour of the two principal forms of tuberculosis. For if phthisis is diffused through the community by the inhalation of dried tuberculous sputa, then it follows that the systematic removal of this with other kinds of filth from the dwellings of the poor, which has been in active progress under sanitary auspices in recent years, will tend to diminish *pro tanto* the number of fresh infections and therefore the resulting mortality. In the case of tabes mesenterica, however, no similar reduction has been effected in the opportunities for fresh infection. On the contrary, inasmuch as cow's milk is now consumed by the children of the poor in much greater quantities than ever before, and as we know that milk is seldom if ever boiled before use, this fact alone would explain the increase of tabes mesenterica—assuming, of course, the correctness of the theory in question.

With regard to preventive measures for the control of the various forms of tuberculosis, Sir RICHARD THORNE gives little encouragement to those who seek assistance from Parliament. In particular he condemns the proposal now sometimes made by even responsible sanitarians that powers should be sought to include phthisis among the dangerous infectious diseases which are compulsorily notifiable to sanitary authorities. He confidently expresses the opinion that compulsory notification of phthisis is impracticable and undesirable in the best interests of public health, and that it would cause infinitely more mischief than it could possibly avert or cure. In this opinion we cordially concur, and we trust that, acting on the advice of their able medical adviser, the Local Government Board will steadily refuse their consent to any proposal of the kind under any circumstances whatever. Sir RICHARD THORNE'S lectures, which we hope to see published in a form befitting their importance, contain thoughtful and sound advice for the preventive treatment of tuberculosis. We would therefore refer our readers to the original lectures for fuller information on a topic which is of supreme national concern.

Annotations.

"Ne quid nimis."

DIPHTHERIA AND ELEMENTARY SCHOOLS.

AT a meeting of the London County Council held on Tuesday last, Nov. 29th, a report of the Public Health Committee was presented to the Council dealing with the large prevalence of diphtheria in London and the connexion of this prevalence with the relatively increased mortality among children at the school age from diphtheria and concluding with a recommendation that the special attention of the Local Government Board and the Education Department should be called to the existing condition of things. Mr. Shirley Murphy's report to the Public Health Committee, on which this recommendation was based, now lies before us. It deals with the many sides of the question exhaustively and, to our mind, demonstrates that the school influence plays an enormously important part in the recent increase of diphtheria in London as well as counting for something in the mortality from whooping-cough and measles. This is a highly important matter to the community and particularly to the medical guardians of the public health and we shall take early occasion to refer to some of the many points of the first medical and statistical interest which are raised by Mr. Shirley Murphy's account of his investigations. One thing may be pointed out now. The medical officer of the London School Board has committed himself to the opinion that the figures relating to diphtheria incidence in other towns do not lend support to views founded upon London statistics. Mr. Shirley Murphy now shows that the same influence may be seen to be at work in a number of other towns in this country and in Berlin, and that London in no way stands alone. After an interesting debate, in which we are glad to note that the councillors taking part all deprecated any idea of acting in antagonism to the London School Board, the recommendation of the Public Health Committee was endorsed by the Council who resolved "that copies of the report of the Council medical officer of health on diphtheria should be sent to the Local Government Board, the Education Department, and the School Board for London, and that the School Board should be invited to appoint some of its members to confer with the Public Health Committee of the Council on the subject matter of the report." As readers of THE LANCET know, the connexion of the increased prevalence of diphtheria with compulsory attendance at school has received for some time the serious consideration of the London County Council.

Digitized by Google

We thoroughly agree in the view which is now expressed by the recommendation of the Public Health Committee in unmistakeable language that the matter is one which urgently calls for the attention of the two government departments concerned—viz., the Local Government Board and the Education Department.

THE PRINCE OF WALES'S HOSPITAL FUND.

IN accordance with the plan set forth by H.R.H. the Prince of Wales, President of the Prince of Wales's Hospital Fund for London, last summer, a committee of gentlemen have visited and inspected carefully the various hospitals which applied, in answer to the advertisement, for a share in this Fund. The committee consisted of the following gentlemen:—Viscount Duncannon, Sir Trevor Lawrence, Bart., Sir Savile Crossley, Bart., Sir Henry Burdett, K.C.B., Mr. Charles Burt, Mr. J. G. Craggs, F.C.A., Dr. W. S. Church, Mr. John Croft, F.R.C.S. Eng., Mr. Frederick M. Fry, Mr. A. D. Fripp, F.R.C.S. Eng., Mr. J. Pierpoint Morgan, jun., Mr. James C. Marshall, Mr. N. C. Macnamara, F.R.C.S. Eng., Dr. E. C. Perry, Mr. T. Pickering Pick, F.R.C.S. Eng., Mr. H. Power, F.R.C.S. Eng., Mr. Albert G. Sandeman, Sir Thomas Smith, Bart., F.R.C.S. Eng., Mr. Julius Wernher, and Mr. Alfred Willett, F.R.C.S. Eng. The various hospitals were visited by two or more visitors, in every instance one of these being a professional man.

HOW TO RESTORE ANIMATION IN ETHERISED SUBJECTS.

A CASE of death which occurred when the patient was under, or had taken, ether, recently reported in the *Brisbane Telegraph*, offers, if the report is correct, food for much thought and for some comment. We cannot vouch for the accuracy of the accounts of the proceedings and we simply give them as they reached us. If the facts are misrepresented our strictures may be unnecessary and, indeed, we hope that such is the case. The scene of the occurrence was a dentist's rooms. The patient, a somewhat stout maiden lady, aged fifty years, required 13 or 14 teeth extracted. The patient had requested a qualified medical woman to give her ether. The evidence of the dentist is that the patient did not take the ether well, symptoms causing anxiety making their appearance early. The administrator states that the patient complained that she was choking. The sequence of events is now somewhat obscure. The administrator states that owing to the unsatisfactory way in which the ether was taken she gave a few whiffs of chloroform which relieved the urgency of the symptoms. She then resumed giving the ether. The dentist, on the other hand, ignores the chloroform, given, it would seem, to a fat patient seated in a chair, but says the patient's state was so unsatisfactory that the administrator removed the mask and *turned round to fill a syringe with ether to inject it*. The italics are ours. He suggested extracting two or three teeth *to rouse the nervous system*. He did extract the teeth, but unhappily the nervous system failed to respond, as might be supposed, to the stimulus of the forceps. Ether was subcutaneously injected and nitrite of amyl was used. The head was lowered, but it appeared almost as if the subcutaneous syringe replaced the all-essential inversion and prompt performance of artificial respiration. We hope the account as we read it is inaccurate for it is a fatal error to lose valuable time at such critical moments. In the first place, the patient should as soon as symptoms of an unsatisfactory nature showed themselves have been inverted, no chloroform should have been given in the sitting posture, and the further administration of ether if attempted at all should only have been done while the patient was reclining. The extraction of teeth in a patient who is on the verge of syncope or in semi-anæsthesia is a step which no experienced or cautious man would consider for a moment, much less practise. The hypodermic injection of ether is not a remedy at all likely to help in such a case. The patient was very nervous and it is possible that she died from fright caused by the suffocative feeling she complained of or from the shock of the teeth being drawn while she was imperfectly anæsthetised, or indeed the syncope may have had no direct connexion with the anæsthetic. Still, as the matter appears in the reported evidence of the magisterial inquiry an unpleasant feeling is left upon the mind that the patient would have had a better chance had other measures been resorted to and with greater promptness. We are not informed how the ether was given. If a cone was used it is probable that the feeling of suffocation was no figure of speech and that the enforced holding of the breath from spasm of the air-passages played no inconsiderable part in producing the fatal issue. Ether improperly given may prove as perilous to nervous and stout subjects as is chloroform. The case is further of interest and importance as death in this sudden way is almost unknown under ether except when due to an overpowering vapour causing spasmodic closure of the glottis.

THE SHEFFIELD SANITARY AUTHORITY AND THE LOCAL GOVERNMENT BOARD.

SHEFFIELD has recently been in communication with the Local Government Board under somewhat peculiar circumstances. We may add that these circumstances have been described in the press under the heading, "Shameful Action of the Local Government Board," which we do not consider to be an accurate description of the situation, though we could have wished that the Board had made its position in the matter clear from the first. This is the story. The two Sheffield fever hospitals were built to accommodate 198 beds, and about a month ago they were actually accommodating 250 patients or more. Under these circumstances the city hospitals committee were empowered by the city council to borrow the money necessary to enlarge the Lodge Moor Hospital. The Local Government Board refused, however, to sanction the loan, and at the same time said that the sewage outfall works of the city at Wincobank did not come up to the requirements of the Board. The case as presented in certain newspaper reports which have been sent to us was one of blackmail. The Local Government Board were represented as having said, "Unless you do this or that with your sewage we shall not give you the necessary facilities for hospital accommodation." This was a capital situation to describe in forcible language, but for the credit of the Local Government Board we hasten to say that no such situation arose. The affair was not so iniquitous and, by the way, not so simple. The Board, we are informed, made no direct refusal of any loan for the extension of hospital accommodation in Sheffield for cases of fever. They postponed further consideration of the matter pending the decision of the city council to make proper arrangements for the purification of the sewage of the city before it went into the River Don and for their apparent dilatoriness they offer a reason. Purification of sewage, if it is to be accomplished to the satisfaction of the Local Government Board, has hitherto meant the land treatment of sewage, while the Wincobank scheme is one for the bacteriological treatment of sewage. The Local Government Board were not prepared off-hand—and, be it remembered, with a Royal Commission actually sitting to decide upon the best method of sewage disposal—to regard the Wincobank scheme as satisfactory, at any rate until they had considered the matter. They are still considering the

Digitized by Google

matter. In the meantime the somewhat sensational statement that the Local Government Board were blackmailing the city to alter its sewage arrangements by the immoral process of withholding permission from the city for a loan until this was done has been discredited by the sanction of the Board having been received to the borrowing by Sheffield of the sum of £24,000 for the much-needed extension of hospital accommodation.

THE TRAFFIC IN OLD HORSES.

WE are very glad to see that the Board of Agriculture has at last taken steps, if not altogether to put a stop to this infamous trade, at least to rob it of most of its horrors. The Board has issued an Order making it unlawful to convey from any port in the British Isles to any place outside the British Isles "any horse which, owing to age, infirmity, illness, fatigue, or any other reason cannot be so conveyed without cruelty during the intended passage and on landing." In dealing with horses which are fit for removal each one must be carried in a separate box of sufficient size and strength, the flooring must be such as to prevent slipping, and slings must be provided so as to be used if necessary. Adequate ventilation, food, and water must be provided and qualified attendants must be carried on every vessel engaged in such trade. The Order is to come into force on Jan. 1st, 1899, and offences under it are to be dealt with as under the Diseases of Animals Act of 1894. The trade as at present carried on is nothing short of a disgrace to this country, and although we would rather see it prohibited altogether the new Order is a great step in advance. It must be remembered that it is not only the gross cruelty to which we object but that these unfortunate animals are shipped to be used as food. The flesh of a diseased and tortured animal cannot be wholsesome, and although—at least we hope so—we do not consume the "delicacies" prepared in this manner in our own country it is neither dignified nor fitting that we should assist in the poisoning of other nations.

HOSPITAL ABUSE IN BRADFORD.

THE authorities responsible for the management of the various medical charities in Bradford have recently held a conference when the great question of ways and means was discussed. As is usually the case the one cry was "more money." Dr. Hime, in a letter published in the *Bradford Observer* of Nov. 26th—and let us give the editor of the *Bradford Observer* every credit for publishing this letter—pointed out that what was wanted was not so much more money as a right use of that which had been obtained already. "Is there," says Dr. Hime, "such a dearth of money when there is such an amount as could allow a share of it being lavished on a home patient who resides in an excellent house and who could afford to invite the poor doctor who attended on behalf of a medical charity to join his hospitable board on Christmas Day? Can there be urgent want of additional funds when there has been enough to spend on a gentleman retired from business and residing at the seaside who could afford to run over weekly to Bradford to receive medical charity?" Obviously we must answer both these questions in the negative. We have already published an exhaustive account of the phases of hospital abuses in Bradford in our issue of March 26th, 1898. There it will be seen that our Special Commissioner found a large amount of abuse to exist and that a great part of it was due to the reckless manner in which subscribers gave away their letters. We are glad to see that Dr. Hime insisted upon this point also in his letter, for it is one of the most important matters with regard to hospital abuse. Nothing apparently has as yet been done in Bradford to remedy these abuses and we fancy that those responsible for the management of the Bradford medical charities would find it well worth their while to set about making a beginning. Doubtless at first subscriptions would fall off, for, as we have said before in these columns, an increase of patients and a certain amount of debt are the means by which many a hospital lives. Hospital letters are an abomination and should be abolished, for the average subscriber is either too indolent or too unacquainted with the facts of the case to be able to say whether the recipient of hospital charity is a worthy object or not.

DELIRIUM FOLLOWING THE ADMINISTRATION OF SALICYLATE OF SODIUM.

AT the meeting of the Société Médicale des Hôpitaux of Oct. 28th M. Rendu reported the case of a woman, aged thirty years, admitted to hospital for rheumatic fever. Salicylate of sodium, 6 grammes a day in divided doses, was given, which quickly relieved the pain and brought down the temperature. In the evening of the following day the patient was suddenly seized with rigors followed by violent delirium with visual and auditory hallucinations. Next morning the patient was in a state of acute mania, with a temperature of 100·4° F. and with pupils unequal and contracted; the urine, which was scanty, was highly albuminous and was charged with indican. Cerebral rheumatism was excluded on account of the absence of high temperature and the tendency to myosis. M. Rendu hesitated between the diagnosis of uræmia and salicylic delirium. The patient had taken only 12 grammes of salicylate of sodium. It was stopped; from that time the delirium diminished and the urine gradually became normal. Simultaneously the articular pains reappeared. The remarkable points are the sudden onset of the delirium and the urinary symptoms. The patient had no neurotic history.

DEATH OF PROFESSOR G. J. ALLMAN.

ANOTHER of the fast diminishing band of old-time "naturalists" has just passed away in the person of Professor G. J. Allman, LL.D., F.R.S., at the ripe age of eighty-six years. The vast difference in the preparation for a career as Professor of Natural History in the first half of the century to that obtaining at the latter end of the same is made manifest by a superficial glance at Professor Allman's earlier life. Of Irish descent and born at Cork, on reaching manhood he first intended to become a lawyer and studied for the bar. An inherent love of nature, however, made law an uncongenial pursuit, and as at that time and indeed for long afterwards the only practical road to a more or less systematic study of the natural sciences in this country was through medicine, he adopted that profession and graduated in 1844. By some fortunate circumstance he did not have to wait long for an appointment, as he was made Professor of Botany at the University of Dublin very soon after taking his degree, and as showing that his medical studies were merely means to an end he does not appear to have at any time practised his profession. Although the chair of Botany is, as a rule, not a very lucrative post it affords the incumbent a good deal of leisure for other studies, and Professor Allman held it for eleven years, when he was offered and accepted the Regius Professorship of Natural History and Keeper of the Natural History Museum in the University of Edinburgh. Professor Allman was elected a Fellow of the Royal Society of London before resigning his chair in Dublin, and not long after taking up his Edinburgh professorship he was made a Commissioner of Scottish Fisheries which he held until that board was dissolved. He was for some years President of the Linnæan Society and President of the British Association for the

Digitized by Google

Advancement of Science in 1879, and he served on the Councils of the Royal Societies of London and Edinburgh and the Royal Irish Academy of Medicine and was Examiner in Natural History for the University of London and many other institutions. His chief original work was done on the hydrozoa and polyzoa, and of this much still remains as authoritative. Perhaps his most important works, in book form at least, are "A Monograph of the Freshwater Polyzoa," 1856, and "A Monograph of the Gymnoblastic Hydroids," 1871–72, both published by the Ray Society. The beautiful figures in the first-named are still reproduced at the present day and are not likely to be superseded. A mere enumeration of his papers and contributions would occupy a very large space and they appeared in the Transactions of most of the well-known learned societies of England, Scotland, and Ireland, as well as in the form of Reports to the British Association, the Museum of Comparative Zoology of Harvard University, and the *Challenger* Commission, and in periodicals like the *Quarterly Journal of Microscopical Science*, *Annals and Magazine of Natural History*, &c. All this labour brought to Professor Allman such rewards as science has to bestow. In 1870 he was granted the honorary degree of LL.D. by the University of Edinburgh and in 1872 received the Brisbane Prize from the Royal Society of that city and in the following year a medal was awarded him by the Royal Society of London, and in 1878 he received the Cunningham Gold Medal from the Royal Irish Academy. Professor Allman's death occurred on Nov. 24th at his residence at Ardmore, Parkstone, Dorset.

ST. MARTIN'S VESTRY AND THE NOTIFICATION OF MEASLES.

A MEETING of the vestry of St. Martin's-in-the-Fields was held on Nov. 10th, when two important matters from a public health point of view were discussed. The London County Council had inquired of the vestry whether they were in favour of applying to "measles" all or any of the following sections of the Public Health (London) Act, 1891—viz., Sections 60 to 66 inclusive, and 69, 70, 72, 73, and 74 (Mins., May 12th, par. 4-iii), and the Public Health Committee recommended: "That the Council be informed the vestry do not think it necessary to place 'measles' in the category of notifiable diseases." However, on the motion being put to adopt this clause Mr. Matthews moved that the word "not" be deleted, which amendment was carried by 7 votes to 3 and becoming the substantive motion was carried also. The vestry of St. Martin's-in-the-Fields has thus definitely committed itself to the notification of measles. This is a step which may or may not be of great value, according to the manner in which the notification is carried out. We have not much faith in the advisability or practical use of notifying measles in the same way as, for instance, scarlet fever or typhoid fever is notified; but in THE LANCET of Oct. 1st we gave an account of an "unorthodox" system of notification as carried out at St. Helens which seemed to promise great things. Briefly the system is this. The head teachers of the borough schools are provided with post-cards on which they notify any suspected cases of measles to the medical officer of health. If the suspicion becomes certainty the teacher receives 3*d.* for every case. Children from infected houses are excluded from school, and Dr. Harris, the medical officer of health of St. Helens, has no doubt of the value of the system. We hope that the vestry of St. Martin's-in-the-Fields will proceed somewhat on these lines, though we are not sure whether they will be able to do so under the provisions of the Public Health Act, 1891. The vestry also decided that the London County Council should be informed that the vestry did not favour the establishment of a bacteriological laboratory specially under the council.

CERTIFICATES UNDER THE WORKMEN'S COMPENSATION ACT.

As will be seen by a letter which we publish in another column the Board of Management of the Norfolk and Norwich Hospital have come to a most praiseworthy decision—namely, that the fee for filling up certificates under the new Workmen's Compensation Act shall be half a guinea, and that for the present the hospital residents shall be responsible for the certificates and shall retain the fees. We hope that every hospital in the kingdom will follow this example and we would urge in addition that a fee, not necessarily half a guinea, should be charged by hospitals for filling up all club certificates and especially school board certificates. The nuisance and the waste of time caused to the resident medical officers in a large hospital by having to fill up club and school board certificates are inconceivable, and the trouble is not lessened by the habit which the educational bodies have of refusing to accept the said certificates or of causing them to be revised by a layman. The certificate question is a form of hospital abuse which it is perhaps more easy to do away with than any other, and we are glad to see that the old city of Sir Thomas Browne has made the first move towards so happy a consummation.

MEMORIAL TO THE LATE MISS MABEL WEBB, M.B. LOND.

ON Nov. 22nd a meeting was held at the Royal Free Hospital to consider the question of founding a memorial to the late Miss Mabel Webb, M.B.Lond., curator of the hospital museum. The Hon. Mr. Justice Bruce, chairman of the committee, presided, and there were present several members of both the committee and medical staff of the Royal Free Hospital and of the School of Medicine for Women, and many past and present students and other friends of the hospital. The chairman, in explaining the objects of the meeting, referred to the many valuable services which Miss Webb had rendered to the hospital. He then called upon Mr. James Berry to move the first resolution, which ran as follows: "That it is desirable there should be a memorial to Miss Mabel Webb, the late curator of the museum at the Royal Free Hospital." Mr. Berry pointed out with what exceptional zeal and energy Miss Webb had devoted herself to her work, and how she had won the regard and affection of all with whom she had come in contact. He suggested that the most suitable means of perpetuating her memory would be to carry out a scheme which she herself had much at heart—viz., the rebuilding and improvement of the museum. This was seconded by Mrs. Scharlieb, M.D. Lond., who paid a tribute to the lofty character and personal charm of the late curator whom she had long known and loved as pupil and friend. Dr. R. H. P. Crawfurd then proposed the following resolution: "That the memorial should take the form of some improvement in the pathological department of the hospital." He explained the details of the proposed scheme to rebuild the museum with the addition of adequate facilities for pathological work and stated that it was estimated that the cost would amount to about £1500. This being seconded by Miss Clapham on behalf of the students, Mr. C. W. Blackman, speaking for the family of the deceased, said that they appreciated very much the kind feeling shown by the proposed memorial, and that they warmly approved of the form which it was intended to take. He also announced the very generous offer on the part of Mrs. Webb to defray the main portion of the expense of the work. A committee was then appointed to carry out

Digitized by Google

the details of the scheme, and it was announced that subscriptions to the amount of nearly £200 had already been promised. Further subscriptions, it was stated, would be gladly received by Mr. C. W. Thies, the secretary of the hospital.

CHLORIDE OF ZINC AS A CAUSE OF DERMATITIS.

EQUALLY interesting and important are cases in which an inflammation of the skin has been set up by the external application of an irritant substance. The list of the substances which may give rise to this artificial dermatitis is very long and it includes several plants, such as Rhus toxicodendron and Primula obconica, various aniline dyes, and numerous mineral matters. This form of dermatitis is important, because it is in many cases the result of the intentional employment of irritants by the patient himself or, more commonly, herself, and also by no means rarely it occurs as the effect of the wearing of particular garments. The commonest variety of this is due to the irritation of aniline dyes, especially the red ones, though in these cases some attribute the dermatitis to the accidental admixture of arsenic with the dye. Occasionally these apparel rashes are due to mineral substances employed as mordants for the dye and an extensive example of this is recorded in another column of THE LANCET. The workmen in a firm were all provided with new overcoats about the same time and they wore them on one particular day which was very wet. In a large number of the cases an inflammation of the skin appeared at the parts touched by the coats—namely, at the wrists and at the neck. The epidemic character and the situation of the rash pointed clearly to the coats as the exciting cause and an analysis of the liquid obtained after soaking a piece of the cloth gave abundant evidence of the presence of chloride of zinc. If only one case had occurred the diagnosis of the cause would have presented much greater difficulty.

THE READING ANTI-VACCINATIONISTS AND THE NEW VACCINATION ORDER.

THE Reading Board of Guardians have, at any rate for the moment, been carried by their anti-vaccination section into an altogether illogical and illegal position—namely, by a large majority, they have practically refused to carry out the terms of the New Vaccination Order. They appear more particularly to resent the statutory powers with which the Local Government Board is vested of fixing the scale of payments to public vaccinators and vaccination officers. It is clearly the feeling of the anti-vaccinationists that those who pay the piper should also call the tune, and, if we mistake not, this section of the Reading guardians has a distinct tendency towards dispensing entirely with the services of the piper, though they are perhaps too wary to verbally admit this. According to the local papers the leader of the dissentient guardians "in language of extreme vituperation condemned the whole system of vaccination which, he said, was most abominable and had proved a failure and exceedingly dangerous." In spite of these views the speaker was anxious to observe that the dissentients had no desire to prevent believers in vaccination from being vaccinated; they had no wish to act as oppressors. But it is perfectly clear to those who read between the lines that even if these be their views they are desirous of obtaining vaccination for the poor who believe in its protective value at as cheap a rate as possible. It is well that the poor throughout the country should realise to the full this attitude on the part of the anti-vaccinationists and that they should comprehend that, not content with having obtained a system by means of which every conscientious objector may procure relief from vaccination, they are bent on depriving the working man of the privilege he has enjoyed for many years of having his child and himself properly protected against small-pox. The public should appreciate what this action on the part of the agitator may mean. It may mean that when an outbreak of small-pox occurs the poor who cannot afford to pay will clamour in vain for protection, and then, perchance, the chickens will come home to roost.

THE EXPENDITURE OF THE METROPOLITAN ASYLUMS BOARD.

IF the system of expenditure, or rather the want of a system of supervision, in the case of the Brook Hospital is a specimen of the work of the Metropolitan Asylums Board it is a serious look-out for the ratepayers of London. The inspector of the Local Government Board, Mr. W. E. Knollys, as one result of his inquiry seems to be astonished at the helplessness of public bodies to control expenditure. He finds that of the large excess of expenditure over estimate in this hospital a liability of at least £25,000 was incurred by the architect without the knowledge or consent of his committee. Some of this, it is admitted, was necessitated by want of time and by defective foundations, but some of it was due to the architect desiring to have the best possible hospital attainable. The inspector also found that the supervision by the committee was defective. The Local Government Board have disallowed the sum due to the architect on account of work ordered on his own responsibility. The report of the inspector is referred to the committee for consideration and report. Dr. Farquharson has done a great service in procuring this inquiry, and it is obvious that a similar inquiry should be made in regard to the other institutions of the Board. It would not be fair to throw the whole blame on the architect. It is obvious that the evils arise out of the system which puts such enormous undertakings for the whole of London on the shoulders of a comparatively small body of men whose time and knowledge of details is limited and who necessarily cause the work to devolve upon their paid officials.

HENRY THOMAS SYLVESTER, M.D. ABERD., V.C.

DR. H. T. SYLVESTER is the possessor of that most valued of almost all decorations, the Victoria Cross. Since his retirement from the army he has lived and carried on his profession in Westminster, but he has recently felt compelled to give up active work. The occasion of his retirement it was felt by his friends should be observed as a fitting opportunity to mark their sense of his services to all who had benefited by his aid, and accordingly on Nov. 25th a large gathering assembled in the mission house of Holy Trinity, Westminster, when Dr. Sylvester was presented with the picture by Desanges, formerly in the Victoria Cross Gallery at the Crystal Palace, representing the act for which he and Corporal Shields received the Victoria Cross. The incident occurred after the assault on the Redan, on Sept. 8th, 1855, when Lieutenant Dynesley was lying severely wounded outside that fort. Sylvester and Shields volunteered to go and bring him in and to do so they had to pass under a very heavy fire, but they succeeded in performing their mission. In addition to the picture Dr. Sylvester was presented with a piece of plate and an album containing the names of the subscribers, among whom were many medical men as well as Mr. Burdett-Coutts, Member of Parliament for Westminster, and Colonel Robert Bruce, C.B., late of the Royal Welsh Fusiliers, Dr. Sylvester's old regiment. The presentation was made by Mr. Burdett-Coutts. Colonel Bruce also spoke and gave an account of the incident represented in the picture. Dr. Sylvester, in reply, gave his version of the affair of which he made very light, saying

Digitized by Google

that though he had done what he could for Lieutenant Dynesley, yet that officer's wounds were such that his case terminated fatally. Our thanks are due in the name of the profession to all those who aided in carrying out this kindly presentation, the inception of which was due to Mrs. Wheeler, one of the guardians of the poor for Westminster.

MEDICAL WITNESSES.

AT a recent meeting of the Shropshire and Mid-Wales Branch of the British Medical Association. Dr Cureton of Shrewsbury, who has been for nearly twenty years a police surgeon, moved the following resolution, which was carried unanimously:—

That in the opinion of this meeting some special accommodation should be provided for medical witnesses in waiting before the grand jury and in courts of assize and quarter session upon the production by them of their subpœnas or other evidence of identity to those in authority; and that copies of this resolution be sent to the Chairman of Quarter Sessions, the Chairman of the Grand Joint Committee of the County Councils and the Clerks of the Peace and chief constables in the area of the branch.

In our opinion this is a much-to-be-desired reform, and not only for medical witnesses, but also for other expert witnesses. To take a prominent instance, the accommodation, or rather the lack of it, at the Old Bailey is disgraceful. There should be a witness-room, or possibly two such, the one for expert witnesses and the other for the ordinary witnesses. The giving of evidence is a duty imposed upon every citizen by law, and one, moreover, which it is only right that every citizen should fulfil apart from any legal obligation, but it is an ordeal which, trying as it always is, should not be made more trying by the lack of a few conveniences which might be easily arranged for. The law's delays are proverbial, but we hope that Dr. Cureton's resolution will in no very long time bear fruit.

THE STUDY OF TROPICAL DISEASES IN LIVERPOOL.

MR. CHAMBERLAIN'S scheme for the teaching of tropical diseases to colonial surgeons, wherever the school may be located, has already borne practical fruit. Mr. Alfred Jones of Liverpool has offered £350 annually to establish and maintain a laboratory in Liverpool for the study of tropical diseases and the scheme will be carried out by a joint committee of the Royal Southern Hospital and of University College. A laboratory for immediate investigation will be built opposite the hospital, whilst prolonged research will be carried on in the pathological laboratory of University College, under the direction of Professor Boyce. A large number of cases from the West Coast of Africa are taken into the wards of the Royal Southern Hospital, as Liverpool, being the centre of the African trade, is in constant communication with West Africa. We again have to congratulate Liverpool on the munificence of her citizens and would direct the attention of medical men about to practice in any capacity on the West Coast of Africa to the opportunity that is being afforded them for obtaining invaluable information.

LECTURES ON MEDICAL RELIEF.

THE fifth of the course of lectures on Medical Relief now being given on Fridays at 4.30 P.M. at the Portman Rooms, dealt with the lunatic asylum, the lecturer being Dr. H. Rayner. The most important stage of treatment in insanity was the incipient stage of the disease, and in Dr. Rayner's opinion insanity should to a large extent be considered a preventable disease; at present cases were not treated early enough. He strongly advocated the establishment of special out-patient departments in connexion with general hospitals and infirmaries; in this way facilities would exist for the treatment of diseases of special organs which helped to develop the mental disease and the association of mental with ordinary disease would tend to the more rapid destruction of the prejudice against insanity as something uncanny. A specially organised hospital ward should be set apart for temporary treatment of those needing special care. "Reception houses" should replace the present workhouse lunatic wards, the 30 such wards now existing in the metropolis being reduced to 5 or 6 reception houses, with a staff of specially qualified medical officers and a specially trained nursing staff, with facilities for calling in the aid of specialists of all kinds. In the cases where the disease was fully developed certified pauper lunatics should be divided at once into classes according to the specia kind of treatment required. The first class would comprise the cases of active mental disorder complicated by bodily disease and needing hospital treatment. The second division would comprise the cases where the mental disorder was acutely active and constant supervision was required. The third division would comprise a much larger number—viz., those sufficiently self-controlled to work at trades involving the use of tools and to be allowed a certain amount of liberty. The epileptic insane, who had also to be provided for separately, the lecturer thought should be aggregated in colonies, as had been done in the State of New York. Dr. Rayner advocated the establishment of the farm colony system as being efficient and economical both in initial expenditure and in maintenance, the need for increased supervision being met by increased productiveness.

LEPROSY IN NEW SOUTH WALES.

WE have just received Dr. J. Ashburton Thompson's report on leprosy in New South Wales for 1896. The report, which is dated Nov. 4th, 1897, states that on Jan. 1st, 1896, 37 persons remained under detention at the lazaret at Little Bay. During the year 9 persons were reported under the Leprosy Act, 1890, as being suspected lepers and 3 of them were eventually admitted to the lazaret under warrants issued by the Board of Health. Five patients died during the year, 4 being natives of Australia of European descent and 1 being a native of Ireland. On Aug. 14th there were 20 Chinese patients in the lazaret and on that day 19 of them were embarked on a cargo steamer to be taken to Hong-Kong, from which place they were removed on board a tug to Canton and there dismissed under supervision of the Consul. There were therefore 16 persons in the lazaret on Dec. 31st, 1896, including 7 natives of New South Wales, 2 English, 1 Fijian, 1 German, 2 Chinese, 1 Japanese, 1 an aboriginal of Tanna, and 1 a native of India. The total number of persons admitted since 1883, when patients first began to be received (though the notification of leprosy was first made compulsory and the detention of lepers provided for by law only towards the end of 1890) is 61. The three patients received during the year were all Chinese, this being the first year since 1890 in which no case in a white person has come to notice. An appendix to the report gives copious clinical and etiological notes of these three cases, together with four full-sized reproductions of radiographs of the hands of two patients suffering from the smooth form of leprosy; the absorption, either complete or partial, of the phalangeal bones is well shown.

FAMILY SPASTIC PARAPLEGIA.

IN a recent number of the *Neurologisches Centralblatt* a very interesting abstract appears of a most important paper on this subject by M. Lorraine of Paris. He first gives a short account of "family" diseases affecting the nervous system. He points out that the lesions are often

Digitized by Google

diffuse, not always affecting definite systems of fibres in the cord, and that transition forms are very numerous. He then considers his special subject—viz., family spastic paraplegia—and his remarks are founded on the observation of cases and on a consideration of a now somewhat extensive literature. Nervous and mental diseases, syphilis, alcoholism, relationship between father and mother, all predispose to the disease. This is found to affect the sexes equally. Infectious disease and traumatism seem occasionally to precede the manifestations of lateral sclerosis. The typical symptoms are spastic gait with increased reflexes and ankle clonus without sensory impairment or interference with the sphincters. Occasionally optic atrophy is observed. Rarely intelligence is defective. The course is usually one of gradually increasing interference with working power and death is often the result of tuberculosis. The only necropsy has been reported by Strümpell, who found primary combined sclerosis of the pyramidal tracts, of the direct cerebellar tracts, and also of the columns of Goll. The former were affected chiefly in the dorsal, the latter chiefly in the cervical, region. Myelitis, compression myelitis, spinal syphilis, and multiple sclerosis, are all to be distinguished, the principal differentiating features being the absence of sensory and sphincter impairment in family spastic paralysis and the presence of a family history. Hereditary cerebellar ataxy presents some features of similarity, but is sufficiently distinguished by the ataxy of the gait. In regard to treatment, warm baths, massage, and rest are recommended, and in certain cases tenotomy, or even it is said neurotomy, may occasionally be useful.

THE NEW SCHOOL OF TROPICAL MEDICINE.

MR. CHAMBERLAIN'S scheme for the establishment of a School for Instruction in Tropical Medicine has naturally attracted a large amount of attention. We have already signified our approval of the proposal to afford opportunities to colonia medical officers and to other members of our profession who intend to practise in tropical districts for the study of the special diseases which they are likely to be called upon to treat. At the same time we have expressed the objections which are being and will be raised to the details of the scheme now under consideration. A judicious protest against certain of these details, over most authoritative and representative signatures, has already reached Mr. Chamberlain's eye and cannot be without its influence upon a Minister so clearly desirous of doing what is right and, above all, what is best for the country. We now publish the correspondence which has taken place between the honorary medical staff of the *Dreadnought* Hospital, Sir Henry Burdett, and Mr. Michelli, the secretary to the Seamen's Hospital Society. This correspondence fully bears out our statement that the medical staff in question have received rude treatment where they might have expected particular courtesy considering the long duration—eighteen, ten, and seventeen years respectively—of their services. Dr. Curnow and Dr. John Anderson, the physicians, and Mr. G. R. Turner, the surgeon to the hospital, naturally objected to the teaching staff of the new school being formed without their previous knowledge; but, as we stated last week, the first intimation they had of what was being done was derived from a letter to the *Times*. The answer given by Mr. Michelli on behalf of the committee to a request for an explanation is simply evasive. He writes that "the statement that 'the teaching staff will consist of the senior medical staff of the *Dreadnought* Hospital at Greenwich as well as of the Branch Hospital, together with a number of teachers specially selected and attached to the new school,' was manifestly intended to convey the meaning that the members of the senior medical staff of both hospitals would have the first option of undertaking the educational work of the staff." We entirely fail to see how a positive statement can "manifestly" be taken to mean a mere proposition, and while expecting to have more to say soon on this matter we content ourselves now by referring our readers to page 1499.

A REPORT from the Pharmacopœia Committee on the proposed Indian and Colonial Addendum to the British Pharmacopœia of 1898, with suggestions for consideration by the medical and pharmaceutical authorities in India and the colonies, was approved and adopted by the General Medical Council on Wednesday. The report contains some very interesting therapeutical information.

THE Plague Commissioners arrived on Saturday last, Nov. 26th, at Bombay by the *Sutlej*. They will hold a few preliminary sittings at Bombay and then in the following week they will proceed to Hyderabad, reaching Calcutta about Christmas. They will return to Bombay later.

THE annual dinner of the Royal Society was held on Wednesday evening last under the presidency of Lord Lister. Lord Curzon of Kedleston and Lord Kitchener of Khartoum were the guests of the society, and received an enthusiastic welcome.

MR. W. S. COLMAN, M.D., F.R.C.P. Lond., was on Nov. 30th elected an Assistant Physician to St. Thomas's Hospital.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE thirty-sixth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Nov. 22nd. The Commissioners present were Lord Llandaff (chairman), the Right Hon. John W. Mellor, Sir John Dorington, Sir George Barclay Bruce, Major-General Scott, Mr. de Bock Porter, and Mr. Robert Lewis.

Mr. R. E. MIDDLETON, in answer to the CHAIRMAN, said that he thought that if the undertakings of the metropolitan water companies were purchased it would entail a loss to the consumers and a still greater loss to the ratepayers if the conditions of revenue spoken of by a witness of the London County Council were carried out—that is to say, if the water rents were reduced to one level for all London, that level being the charge made by the West Middlesex Company.

In answer to Mr. MELLOR the witness said that if the companies were sold to a public authority he did not think that in estimating their value the question of the liability to injury by frost ought to be taken into account.

Mr. MELLOR suggested that if a water company were sold all accidents which might happen to the undertaking ought to be taken into account. The witness thought otherwise. Accidents which might happen were not the act of the company but the act of God. They were not the fault of the company. The witness admitted, however, that if the financial conditions of the company were investigated during a period of years in which a frost happened, and if the income of the company were thereby reduced, no doubt that loss ought to be taken into consideration.

In answer to Sir GEORGE BARCLAY BRUCE the witness said that the arbitrator in coming to a conclusion as to the just price would have to consider the past revenue, and inasmuch as droughts and frosts had affected the revenue in the past they should to that extent be taken into account.

Mr. LEWIS suggested that if the companies charged for water whether it was supplied or not drought would not affect their revenues. The witness said that a company's revenue was affected if they had to purchase water from another company and only in that case, and the CHAIRMAN pointed out that the Commissioners had heard that the East London Company had continued their charges for high services though all high cisterns were without water. The

Digitized by Google

CHAIRMAN asked the witness whether in the case of purchase of the undertakings by one authority some saving would not be made in the cost of management and maintenance. The witness replied that in his opinion a board which had been in existence a great many years would be more likely to be economical than one of a fleeting character which was unlikely to effect economies. He thought, moreover, that municipal management did not as a rule effect economies. That argument he admitted would not apply to the case of purchase by a special board of experts created *ad hoc*. With regard to the compensation of directors and officials which it was suggested would become an expense to the purchasing authorities Mr. MELLOR pointed out that it would be necessary for the new board to keep their officials. If they still employed them there would be no occasion to pension them.

Sir GEORGE BARCLAY BRUCE suggested that as there would be fewer officials some at least would have to be pensioned off, but Mr. R. LEWIS pointed out that pensions so paid to officials who were not wanted would not lead to any increase of expenditure because in the case of such a retired official the vacancy would not be filled.

Mr. DE BOCK PORTER suggested that if all the undertakings were under one management fewer officials would be required. The witness replied that he thought otherwise and that he believed more officials would be required.

Mr. DE BOCK PORTER referred to the great expense incurred in the collection of water-rents under the present system, and the witness admitted that there were at present a large number of collectors, and that if the water-rents were collected with the municipal rates the cost of collection would be diminished.

Mr. LEWIS suggested that it would not be necessary that eight secretaries, eight accountants, and eight cashiers should be employed if the undertakings were under a single management.

In answer to the CHAIRMAN the witness said that he did not remember Mr. Banbury's scheme of purchase, but he thought that the shareholders of the present undertakings were entitled to compensation for prospective value.

Sir GEORGE BARCLAY BRUCE suggested that the purchaser would likewise be entitled to a consideration for prospective diminution of income should it be proved that the undertakings would probably produce less than they have in the past.

The question arose as to the effect which a rise in the rates would produce on the water companies' undertakings. The witness said he was utterly unable to answer definitely what the effect of this would be on the companies' profits.

Sir JOHN DORINGTON asked whether in the case of purchase a valuable ratepayer would be lost, but it was pointed out that the London County Council pays rates and the water companies also have at present to pay rates in the counties of Middlesex, Surrey, Essex, and Kent, where some of their property is situated.

Mr. R. LEWIS raised the question of the effect of the sinking fund clause on the future financial state of the companies, and Mr. DE BOCK PORTER pointed out that the operation of the fund in the future would be very large and said that it would be impossible in the case of arbitration to overlook that fact. He also pointed out that as a matter of fact the present method of collecting the water rents is a very expensive one and at the present time costs no less than £50,000 a year.

The CHAIRMAN examined the witness with regard to the effects of purchase on the outside authorities. The witness pointed out that the mains of the companies had not been laid with any idea of supplying water in bulk beyond the metropolitan area. They had been laid across the county boundary in all directions and in many cases there were a very large number of mains crossing the boundary. Some of these supplied from the outside inwards; others from the inside outwards; some crossed in both directions. If a supply were given in bulk from the inside outwards many of these mains would have to be relaid and meters would have to be placed on them. In the case of the East London Company the chief mains passed from Essex into the county of London, the county boundary being the River Lee and the company's chief pumping station at Lee Bridge being in the county of Essex. (Part of the Lee Bridge station is as a matter of fact in the county of Middlesex. A description of this station has already appeared in THE LANCET.) With regard to the New River Company the witness said that all the pumping stations were entirely outside the county of London (the pumping station at New River Head must have been forgotten by the witness). In the case of the West Middlesex Company about twenty main pipes cross the boundary in West Middlesex and there were some sixty-one smaller mains, about half of which were used for the supply inside the county of London and half of which supply the outside area and which necessarily cross the boundary to do so. In the case of the Chelsea Company the witness pointed out that the works are almost entirely outside the county of London and the whole supply is given within the county of London. In the case of the Southwark and Vauxhall Company the service reservoirs are situated at Nunhead and at Forest Hill in the county of London. There is no system of mains in existence by which water could be supplied in bulk from these reservoirs for the use of the county of Surrey. The mains at present passing through Surrey are used to supply mains both inside the metropolis and outside and they would have to be cut off and reconnected in order to make them useful for supplying Surrey. The length of boundary line between the metropolis and the county of Surrey in the case of the Southwark and Vauxhall Company is about three and a half miles. The Lambeth Company supplies a distance of about fourteen and a half miles on the boundary, about seventy streets cross the boundary, and some of these have two or more mains laid in them. The supplies of the Kent Company are drawn entirely from wells. The largest pumping station is at Deptford, and there are pumping stations at Plumstead, Shortlands, Crayford, Farnborough, and Wilmington in the county of Kent. Plumstead is situated in the county of London.

The CHAIRMAN asked the witness whether he could give an estimate of the expense of remodelling the distribution of water so as to enable the county of London if it were the purchaser of the metropolitan companies to supply all the outside authorities in bulk. The witness replied that he could not give an estimate, that the cost would be very large—it would at any rate amount to several hundreds of thousands of pounds, probably to nearly a million.

Major-General SCOTT asked whether it would not be possible for the companies to put in a statement giving the cost. The witness said that they could not do so without considerable trouble.

In answer to the CHAIRMAN the witness said that in his opinion a supply in bulk to the county of London would be practicable but it would be inconvenient and expensive. The witness went into considerable detail with regard to a scheme suggested by Sir Alexander Binnie for dividing the water-supply of the Lambeth Company in such a way that the county of London and the metropolitan authority could each have control of their own supply. In order to make matters clear he described the situation of the reservoirs, filter-beds, and pumping-stations of the Lambeth Company, which have been already described in THE LANCET. With regard to the Staines reservoir scheme the witness said, in answer to Mr. DE BOCK PORTER, that up to the present time 620 acres have been acquired. To complete the scheme 4500 acres would be required. The witness handed in a table giving his estimate of the cost of supplying 185½ millions of gallons daily from the Thames. This estimate was made for comparison with one given by Sir Alexander Binnie.

COMPARISON OF SIR A. BINNIE'S AND MR. MIDDLETON'S ESTIMATES OF COST OF SUPPLYING 185½ MILLION GALLONS PER DAY FROM THE THAMES.

To Supply 185½ Million Gallons per Day.

	SIR A. BINNIE'S ESTIMATE.				
	Million gallons.	Total.	Cleansing.	Bottom and evaporation.	Net.
Capacity	8000	— 8000	— 2000	— 1000	= 5000
Less existing capacity	866				
Total capacity	7134 at £380 per million gallons				£2,710,920
*Annual pumping into reservoirs (1893)	10,566 at 5s. per million gallons = £2639. Capitalised at 30 years				79,170
†Distributing 55½ million gallons per day	20,257½ at £2 10s. per million gallons = £50,644. Capitalised at 30 years				1,519,320
Total					£4,309,410
Pumping machinery for distribution					395,775
Total					£4,705,185

Digitized by Google

Note by Sir A. Binnie.

The above estimate includes nothing for the capital cost of the engines and accessories to pump the 55,500,000 gallons for distribution, but, as will be seen from the estimate of Messrs. Hunter and Fraser (Royal Commission, appendix C 66, page 478, second column), they apparently include a capital sum of £1,212,300 as a total in 1941 for this purpose.

At this rate £395,775 should be added to the above.

Note by Mr. Middleton.

* The charges for pumping to store have been capitalised on the draft during the year of greatest drought, not on the average of years, as they should have been.

† This capitalisation has been made on the cost of pumping 55½ million gallons per day, which will not be reached until the year 1916. It should be on the average less than half that quantity. The sum so arrived at should be discounted for present value.

To Supply 185½ Million Gallons per Day.

MR. MIDDLETON'S ESTIMATE.

	Million gallons.	Total.	Cleansing.	Bottom and evaporation.	Net.
Capacity	5239	— 5239	— *Nil.*	— 476	= 4753
Less existing capacity	866				
Total capacity... ...	4373 at £300 per million gallons ...				£1,311,900
*Pumping into reservoirs	4431 million gallons, average for 16 years, at 7*s.* 6*d.* per million gallons = £1661 12*s.* For 16 years...				26,586
*Cost of pumping to supply a quantity increasing from *nil* to 55½ million gallons per day during 16 years, at £2 4*s.* per million gallons					320,178
Total					£1,658,664
Pumping machinery for distribution					181,980
Total					£1,840,644
*If the pumping charges be capitalised at 30 years' purchase a sum of £307,524 must be added. This has been done by Sir A. Binnie, but I do not concur					307,524
Total					£2,148,168

The thirty-seventh sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Monday, Nov. 28th. The Commissioners present were Lord Llandaff (chairman), the Right Hon. J. W. Mellor, Sir John Dorrington, M.P., Sir George Barclay Bruce, Major General Scott, Mr. de Bock Porter, and Mr. Robert Lewis. The whole of the sitting was occupied by the examination of Mr. Middleton who put in an enormous number of tables relating to the cost of the storage reservoirs which would be necessary should the Thames coutinue to be used as a source of extra supply and a number of tables relating to the cost of Sir Alexander Binnie's scheme for bringing water from Wales.

In answer to the CHAIRMAN the witness said that in his opinion it would cost very much more to bring a supply from Wales than to obtain an equal amount from the Thames. He thought that the sources of the valleys of the Lee and of the Thames would afford an adequate supply of water for the next fifty years.

In answer to Mr. MELLOR the witness said that he thought that on an average 400,000,000 gallons could be taken daily from the Thames.

In answer to the CHAIRMAN the witness said that water from Wales would have to be filtered. The Chairman remarked that he had understood that the Welsh water was to be "pure nectar."

Mr. BALFOUR BROWNE pointed out that it was proposed to filter the water derived from Wales but the cost of doing so would be less than the cost of filtering Thames water.

In answer to the CHAIRMAN the witness gave an estimate of the amount of water which he thought could be obtained from the existing sources. It was briefly as follows:—

	Gallons.
From the Thames	400,000,000
From the Lee	52,500,000
From wells in the Lee Valley	40,000,000
From wells in the Kent Company's district...	27,500,000
From the Southwark and Vauxhall well at Streatham	2,000,000
From other wells in Kent	123,000,000
	645,000,000
In addition wells sunk in the chalk would yield a supply of	190,000,000
Total estimated supply... ...	835,000,000

The estimate given by Lord Balfour's Commission was 420,000,000 gallons daily.

The witness said that he would have seen no objection to taking water at the rate of 400,000,000 gallons daily from the Thames this year. (But for the space of three months the natural discharge of Teddington Weir was not 400,000,000 gallons.) There was statutory power now to take 185,000,000 gallons, and the witness did not think that the loss of another 130,000,000 gallons per day would be appreciable in the tidal part of the Thames.

In answer to Sir GEORGE BRUCE the witness said that the amount of the estimate given by the London County Council for a water-supply of 123,500,000 gallons per day was £21,000,000, whilst the cost of putting up storage reservoirs to supply a like amount from the Thames would not be much over £6,600,000.

With regard to the amount of water which could be obtained from the valley of the Lee the witness said in answer to the CHAIRMAN that he did not think that 52,500,000 gallons daily was an extravagant amount to estimate as the supply to be derived from the River Lee. He did not admit that the Lee had been reduced to a shocking state, but its condition during the present year had been exceptional.

In answer to the CHAIRMAN the witness admitted that there had been an insufficient amount of water to supply the East London Waterworks Company, but thought that more storage reservoirs should be put up in the Lee Valley. With regard to the Thames the witness gave it as his opinion that the flow over Teddington Weir could quite safely be reduced to an amount less than 200,000,000 gallons daily. If there was no flow of water down the Thames the sewage at the lower part of the river would oscillate backwards and forwards. With regard to the control of the water drawn from the sources of supply the witness suggested that it might be managed by an amalgamated board and the method of management might be left with the companies. His suggestion was that a board similar to that constituted for the management of the Staines reservoirs should be appointed and that this board should decide in what way the water should be distributed, from what source it should be derived, and how much each company should be empowered to get from the Thames or elsewhere. The witness thought that in future Parliamentary powers for the abstraction of water from the Thames should not be given to any one company but to the whole eight companies in such proportions as the board should determine. The companies should amalgamate for the purpose of obtaining water. This amalgamation would not interfere with the present financial arrangements of each separate company. This proposal the witness put forward as his own view of the best solution of the difficulties which might arise on application for powers for further abstraction of water from the Thames.

In answer to the CHAIRMAN the witness said that he attached little importance to the fact that during periods of flood much agricultural sewage came down the river and he saw no objection to pumping flood water into the reservoirs. The amount of pollution which existed in the flood water of the Thames would not, in his opinion, be injurious.

The witness described the present storage reservoirs belonging to the metropolitan water companies. The storage capacity belonging to the various companies for Thames water was stated to be as follows:—

	Gallons.
Southwark and Vauxhall	136,000,000
Lambeth	125,000,000
East London	5,000,000
West Middlesex	397,000,000
Grand Junction	64,500,000
Chelsea	140,000,000

(The New River and the Kent companies do not draw any water from the Thames at present.)

The above figures represent the existing storage capacity now at work, exclusive of the Staines scheme or the works now under construction at the Southwark and Vauxhall Company's station. The additional storage either in process of construction or authorised is 327,000,000 gallons for the Southwark and Vauxhall Company, 335,000,000 gallons for the Lambeth Company, and 3,300,000,000 gallons for the Staines reservoirs.

The Commissioners adjourned till Tuesday, Nov. 29th.

The thirty-eighth sitting was held on Tuesday, Nov. 29th, when Mr. Middleton was still under examination. The

Digitized by Google

witness again put in many tables and was cross-examined by Lord R. Cecil on behalf of the Hertfordshire County Council. The next sitting will be on Monday next, Dec. 5th.

A TROPICAL SCHOOL OF MEDICINE.

WE have received for publication the following correspondence which has taken place between representatives of the committee of the Seamen's Hospital Society and the honorary visiting staff of the *Dreadnought* Seamen's Hospital, Greenwich. The bearing of these letters upon the scheme for a Tropical School of Medicine which we have recently discussed and are still discussing in our columns is obvious.

13th July, 1898.

DEAR SIR HENRY BURDETT,—In your letter in the *Times* of Monday last on the subject of a proposed School for Tropical Diseases in London, you say:—

"The teaching staff will consist of the senior medical staff of the *Dreadnought* Hospital at Greenwich, as well as of the Branch Hospital, together with a number of teachers specially selected and attached to the new school."

Will you be so kind as to inform me upon what authority you make this statement, in so far as it refers to the medical staff of the *Dreadnought* Hospital?

Apologising for troubling you, believe me, yours truly,

J. ANDERSON.

15th July, 1898.

DEAR DR. ANDERSON,—As my letter was written under instructions from the committee of the *Dreadnought* Hospital I have referred your letter of the 13th instant to them and will let you know in due course.

Believe me, yours very truly,

Dr. Anderson, 9, Harley-street. H. BURDETT.

The Lodge, Porchester-square, W.,
18th July, 1898.

DEAR DR. ANDERSON,—With further reference to your letter of the 13th inst., I am desired to say that it is the intention of the committee of the *Dreadnought* Hospital to give the opportunity to the senior medical staff of both their hospitals to take part, if they thought well, in the work of instruction at the School for Tropical Diseases about to be established at the Branch Hospital.

Believe me, yours very truly,

Dr. Anderson. HENRY C. BURDETT.

Dreadnought Seamen's Hospital,
Greenwich, S.E., 14th July, 1898.

DEAR SIR,—I am directed to inform you that upon the representation of the Colonial Office, the committee of management of the Seamen's Hospital Society have resolved to establish a school for the study of tropical diseases in connexion with their Branch Hospital in the Royal Victoria and Albert Docks. This will involve the erection of school buildings and the enlargement of the hospital to 45 beds.

I have been directed to ask you to coöperate in this movement and to confer with the other members of the society's honorary medical staff, with a view to suggest to the committee of management arrangements as to the educational staff and the general system of the school. The committee will propose as far as possible to concentrate cases of tropical disease at the teaching centre. Yours faithfully,

J. Curnow, Esq., M.D., F.R.C.P. P. MICHELLI, Secretary.

P.S.—I enclose a letter and a leader which appeared in the *Times* of July 11th in reference to the scheme.

9, Wimpole-street, Cavendish-square, W.,
16.7.98.

DEAR SIR,—I am in receipt of your letter of the 14th inst., with the cuttings from the *Times* of July 11th, which I had already seen in the *Times* of that date. Would you oblige me by informing me whether Sir Henry Burdett personally, or the hospital committee, are responsible for the statement that "the teaching staff will consist of the senior medical staff of the *Dreadnought* Hospital at Greenwich," &c.? The publication of such a statement without my being asked, in a scheme of which I knew nothing before I saw it in the *Times*, seems to me most discourteous to myself and intended to convey an unwarranted impression to the public.

I also wish to know if the committee seriously propose "to concentrate cases of tropical disease" at the Branch Hospital and thus deprive the parent hospital of its one distinctive feature.

Believe me to remain, faithfully yours,

JOHN CURNOW, M.D

P. Michelli, Esq., Secretary, Seamen's Hospital Society.

Dreadnought Seamen's Hospital,
Greenwich, S.E., 21st July, 1893.

DEAR SIR,—In reply to your letter of the 16th inst., I am directed to say that Sir Henry Burdett's letter was written upon information supplied to him by the committee of management, and the statement that "the teaching staff will consist of the senior medical staff of the *Dreadnought* Hospital at Greenwich, as well as of the Branch Hospital, together with a number of teachers specially selected and attached to the new school"; was manifestly intended to convey the meaning that the members of the senior medical staff of both hospitals would have the first option of undertaking the educational work of the school.

Yours faithfully,

P. MICHELLI, Secretary.

J. Curnow, Esq., M.D., F.R.C.S.,
9, Wimpole-street, Cavendish-square, W.

Dreadnought Seamen's Hospital,
Greenwich, July 18th.

To the Editor of the Times.

PROPOSED SCHOOL FOR TROPICAL DISEASES.

SIR,—Sir H. Burdett in your issue of July 11th, writing of a proposed School for Tropical Medicine, states that "the teaching staff will consist of the senior medical staff of the *Dreadnought* Hospital at Greenwich, as well as of the Branch Hospital, together with a number of teachers specially selected and attached to the new school." This was the first intimation of any kind that we had that such a scheme was on foot, and the statement was made without our authority or consent.—Yours faithfully,

JOHN CURNOW, M.D., F.R.C.P., } Visiting
JOHN ANDERSON, M.D., F.R.C.P., } Physicians.
G. R. TURNER, F.R.C.S., Visiting Surgeon.

9, Wimpole-street, W.,
25.7.98.

DEAR SIR,—I cannot accept your letter of the 21st inst. as a satisfactory explanation of the position. Sir Henry Burdett's statement that "the teaching staff will consist of the senior medical staff of the *Dreadnought* Hospital at Greenwich, &c.," is quite positive, and is an unauthorised statement. It will not convey to the readers of the *Times*, who I may point out are asked for subscriptions in aid of the committee's scheme, that it manifestly means "that the members of the senior medical staff of both hospitals would have the first option of undertaking the educational work of the school." Such an explanation should be publicly given in the *Times* by either Sir H. Burdett, who has apparently been misinformed, or by the committee.

As you have not answered my second question I must ask it again and I will put it in the following form. Has the committee decided to concentrate as far as possible the cases of tropical disease which alone give its distinctive character to the *Dreadnought* Seamen's Hospital at Greenwich, and has this course of action been determined on without consulting either Dr. Anderson or myself?

Faithfully yours,

JOHN CURNOW, M.D.

P. Michelli, Esq., Secretary, Seamen's Hospital Society.

Dreadnought Seamen's Hospital,
Greenwich, S.E., 28th July, 1898.

DEAR SIR,—In reply to your letter of the 25th inst., it appears that you and your colleagues have already taken the most efficient method of undeceiving the readers of the *Times* by your letter explaining that the senior staff of the *Dreadnought* were not consulted on the question of their joining the educational staff before Sir Henry Burdett's letter was written to the *Times*, and that the statements therein were made without their authority or consent. It does not, therefore, seem that any good purpose could be served by reiterating the fact, even if the *Times* would accept a second disclaimer.

Your question with regard to the tropical cases at Greenwich is rather one for the committee than for me to answer,

Digitized by Google

and I will take care that your letter is laid before the Board at their next meeting.—Yours faithfully,

P. MICHELLI, Secretary.

J. Curnow, Esq., M.D., F.R.C.P., 9, Wimpole-street, W.

Oct. 10th, 1898.

DEAR SIR,—Referring to the proposed School for Tropical Medicine at the Victoria and Albert Docks and Mr. Michelli's letter of July 14th, we think our letter to the *Times* of July 20th was a plain statement of facts. We see nothing to regret on our part, and if there is any meaning in plain English, Sir Henry Burdett's words can have but one interpretation, i.e., that the senior staff of the *Dreadnought* were to be on the teaching staff of the proposed school.

On July 15th he wrote Dr. Anderson that his letter to the *Times* was written under instructions from the committee of the *Dreadnought;* a committee, we would remind you, who had not had the courtesy to let us know that such a scheme was on foot, still less to ask for our coöperation until some five days after the vice-president's letter appeared in the lay press and he had been asked for explanation by Dr. Anderson.

We beg to ask the committee, as Dr. Curnow has twice already asked the secretary, whether they have decided to concentrate the cases of tropical diseases at the Branch Hospital and have done this without consulting the visiting physicians of the parent *Dreadnought* Hospital.

It is impossible for us to give any answer to a request for coöperation until we have been put in full possession of the details of the proposed school.—Believe us, yours faithfully,

J. CURNOW.
J. ANDERSON.
G. R. TURNER.

The Chairman of the *Dreadnought* Hospital Committee.

Dreadnought Seamen's Hospital,
Greenwich, S.E., 17th Oct., 1898.

DEAR SIRS,—I am instructed to acknowledge the receipt of your letter of the 10th inst. which was laid before the general committee at their meeting on Friday last.

The committee regret that you still feel aggrieved by Sir Henry Burdett's letter which was published in the *Times* of July 11th.

They also much regret that you do not feel able to signify your wish to coöperate with them in carrying out the scheme of H.M. Secretary of State for the Colonies for the establishment in connexion with the society's Branch Hospital of a school for the study of tropical diseases.

The details of the scheme must necessarily remain open for consideration by the committee which will be appointed to manage the school.

I am, dear Sirs, yours faithfully,

P. MICHELLI, Secretary.

John Curnow, Esq., M.D., &c.
John Anderson, Esq., M.D., &c.
G. Robertson Turner, Esq., F.R.C.S., &c.

9, Wimpole-street, Cavendish-square, W.,
29th Oct., 1898.

DEAR SIR,—We beg to acknowledge the receipt of your letter of the 17th inst.

It is true we are aggrieved by the entirely unauthorised statement contained in Sir Henry Burdett's letter published in the *Times* of July 11th last; but we are still more so by the committee's want of courtesy in not asking the opinion of the senior medical staff of the *Dreadnought* Hospital at any time during the inception of their scheme before the letter was written, and for which lack of courtesy no apology has been offered or regret expressed.

The question as to the concentration of tropical cases at the Branch Hospital and consequent starvation of the parent hospital at Greenwich in its one distinctive feature has not yet been answered, although three times asked, and we press your committee for a definite reply upon this point, after the receipt of which we will not trouble them with further correspondence. We are, dear sir, yours faithfully,

JOHN CURNOW.
J. ANDERSON.
G. R. TURNER.

The Secretary, *Dreadnought* Seamen's Hospital,
Greenwich.

Dreadnought Seamen's Hospital,
Nov. 28th, 1898.

SIRS,—Not having received any reply to the question we pressed upon you in our letter of Oct. 29th last we are sending the correspondence that has taken place between us to the press for publication. In doing so we wish to remind you that we have performed the medical and surgical work of the *Dreadnought* Hospital for eighteen, ten, and seventeen years respectively. We are, Sirs, yours faithfully,

JOHN CURNOW.
J. ANDERSON.
G. R. TURNER.

To the Committee, *Dreadnought* Seamen's Hospital,
Greenwich.

THE USE OF THE ROENTGEN RAYS ON THE BATTLE-FIELD.

THERE was a large attendance at the Camera Club, Charing Cross-road, on the evening of Monday, Nov. 28th, when in simple language suited to a lay audience Major Beevor, R.A.M.C. (Surgeon-Major, Royal Scots Guards), demonstrated before the members of the club and their friends the result of x-ray work during the Afridi campaign. There never existed, he said, a braver set of men or more skilful artists with modern firearms than the Afridis, and consequently there was no lack of wounds for the surgeon's attention. It was not only bullets, however, that these men used as messengers of death, but, as Major Beevor pointed out in a previous lecture, all sorts of objects—pieces of telegraph wire, buttons, and, in fact, anything hard. The lecturer dwelt on the difficulty which attended the localisation and finding of foreign bodies in the animal organism, and remarked that though modern surgery had progressed greatly and chloroform had done a great deal towards the alleviation of human suffering he humbly maintained that of late years no invention had come to the fore in this respect so forcibly as that which was known as the x rays. To be able to localise, to find the size, and to operate directly upon a foreign body in the human organism by means of this invention was an incalculable benefit to both surgeon and patient.

The lecture took the form of a running commentary on a series of radiograms exhibited by means of the electric lantern, and without reproducing these pictures it is difficult to make the cases intelligible to our readers, but Surgeon-Major Beevor's remarks embodied some information of value to the medical profession and we pick out such items of interest as may have a useful bearing upon x-ray work and surgery.

In one case a bullet was shown embedded in the tissues of the popliteal space. This injury caused a great deal of swelling and irritation around the knee-joint. The bullet after striking the tibia lodged in the popliteal space a little above the condyles of the femur and could not be discovered by means of a probe. By the x rays it was found within an inch of the surface of the skin. Had not these rays been used it would probably have been necessary to amputate. The swelling was very marked and the radiogram showed to what an extent bones can be pushed apart and the supporting ligaments stretched by inflammation and irritation of a joint. The space between the femur and the tibia was greatly exaggerated and the patella was high up above the condyle of the femur, notwithstanding the fact that the leg was flexed. As showing the conditions under which operations have to be performed on the battlefield, the temperature at this time was about 110° F. in the shade, and there were about 400 men to look after and some 110 dead men to be buried. Another radiogram showed a bullet which had entered the inner side of the biceps. This could not be found by a probe, as it had slipped down into the sheath of the tendon and become embedded. So incorporated was it with the fibrous material that an hour and a half were occupied in dissecting it out. The superiority of the x rays over the probe in some cases was shown by the case of a man from whose instep four pieces of telegraph wire were removed. A small piece of flint was afterwards extracted and it was thought that the patient would recover. Three months later the man was about on crutches but he complained that he could not put his heel to the ground. On examination with the fluorescent screen it was found that a piece of bone was impacted in the periosteum beneath the heel. This could not possibly have been found with a probe. Another case shown was that of a sergeant of Sikhs, who was struck in the elbow while wearing a poshteen—a

Digitized by Google

garment made of goat-skin. If the weather is fine this coat is worn with the hair next the body, but if the weather is damp it is turned inside out and the hair worn outside so as to protect the leather from the wet. In this case the bullet carried into the muscles a mass of leather and hair, blood poisoning supervened, and the joint swelled to such an extent (some 12 in. in circumference) that it was impossible to find a foreign body with a probe. By the use of the x rays, however, the foreign body was located and finally removed. The man made a good recovery. The radiogram of an officer's hand was shown to demonstrate the fact that small quantities of a compound of lead, such as that incorporated in the material used for lead plaster, offer resistance to the x rays. The radiogram was taken while the hand was bandaged and the strips showed as distinct rings around the fingers. A radiogram of the leg of General Woodhouse was shown to illustrate the fact that not only bone but fibrous material will break up a bullet. It is interesting to note that while the bullet in this case was being extracted thirteen bullets passed through the tent in which the operation was being performed.

An interesting discussion followed in which Mr. Cadett, Mr. H. H. Massey, M.R.C.S. Eng., Mr. Inwards (late president of the Meteorological Society), the chairman, Mr. Wilson Noble, Mr. A. A. Campbell Swinton, Mr. Godfrey (the secretary of the Camera Club), and others joined. In this discussion it was suggested that light dynamos to be worked by hand power should be constructed for use on the battle-field and in military operations, that in some cases electric power might be obtained from ships of war; that chemists should direct their attention to the manufacture of sensitive plates more suited to x-ray work than the ordinary photograph plates, that the Wimshurst machine might be used, and that the Government should be asked to facilitate in every possible way the use of the Roentgen rays in military campaigns.

In his reply Major Beevor spoke of the uselessness of photographic films in hot climates and the difficulties attending transport of the apparatus. He mentioned that a dynamo for use by hand had been used in the Soudan and had proved fairly satisfactory. The Government of India had afforded him every facility for carrying on the work.

Hearty votes of thanks to the lecturer and to the chairman terminated the proceedings. Credit is due to Mr. Godfrey for his success in organising this gathering which greatly exceeded in numbers the ordinary attendance at the lecture evenings of the Camera Club.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

A MEETING of the Council of this Fund was held at the Mansion House on Monday, Nov. 28th. In the unavoidable absence of the Lord Mayor, the Bishop of Southwark presided.

The report of the Council for the year ending Oct. 31st, 1898, stated that the twenty-sixth year of collecting this Fund had resulted, under the presidency of the Right Honourable Sir Horatio D. Davies, K.C.M.G., M.P., Lord Mayor, treasurer, in a total of £40,397 2*s.* 10*d.* The Rev. C. J. Ridgeway, M.A., of Christ Church, Lancaster Gate, headed the list of contributions with £1,367; the Rev. Canon Fleming, B.D., of St. Michael's, Chester-square, collected £1268; the Rev. J. Storrs, M.A., of St. Peter's, Eaton-square, £681; the Rev. Prebendary Eardley-Wilmot, M.A., of St. Jude's, South Kensington, £623; and the Rev. F. E. Ridgeway, D.D., of St. Peter's, Cranley Gardens, £501. Sir Saville Crossley, Bart., again most generously contributed £500, a like sum of £500 being sent by him to "The Prince of Wales's Hospital Fund"; £300 were received from A. G. P.; "Delta" sent his twentieth donation of £200; and Mr. George Herring sent £200.

On the motion of Sir HENRY BURDETT the following resolution passed in committee was added to the report.

Resolved unanimously:—

That before proceeding to business and having this day heard of the death of their much-esteemed colleague Sir Stuart Knill, Bart. the committee desire to record their regret and request the secretary to convey to Lady Knill and her family their sincere sympathy and condolence.

Alderman Sir H. D. DAVIES, the late Lord Mayor, was elected to fill a vacancy on the Council. June 11th was recommended as the date on which to hold Hospital Sunday in 1899. The annual general meeting of the constituents of the Fund was fixed for Monday, Dec. 12th.

PUBLIC VACCINATORS AND THE NEW VACCINATION ACT.

AN IMPORTANT MEETING OF PUBLIC VACCINATORS AT MALTON.

ON Wednesday afternoon last a meeting of public vaccinators was held at Malton to take into consideration the remuneration which should be granted in urban and rural districts. Dr. William Colby, J.P., of Malton, was voted to the chair and there were also present Mr. Malvin (Scarborough), Mr. Scott (Thornton Dale), Mr. Stuart (Great Ayton), Mr. J. T. R. Miller (Malton), Mr. W. S. Sprent (Slingsby), Mr. Comber (Pickering), Dr. Glen and Dr. Fulton (Middlesbrough), Mr. Norris (Sherburn), Dr. Gramshaw (Stillington), Mr. Hine (South Cave), Mr. Todd (Selby), Mr. Wetwan (Bridlington), Mr. Haworth (Filey), Dr. Hope (Hutton-Buscel), Dr. Dougall (Welburn), Dr. McCracken (Coxwold), and Dr. Adams (Rillington).

Mr. SPRENT, who had convened the meeting, said that the result of his communication had been to get replies from every union in the North and East Ridings, while of 127 public vaccinators in the two Ridings he had received replies from 118 entering into details on the points to be discussed at the meeting. In cases where there was no representation the unions were in perfect accord with the object of that meeting and gave him authority for their support in certain resolutions. 75 per cent. of the public vaccinators seemed to be very strongly in favour of a mileage fee and against the minimum fee laid down by the Local Government Board. The Aysgarth Union suggested that the 1*s.* fee should be 2*s.* 6*d.*, while they accepted the 5*s.* fee and suggested 1*s.* per mile after the first mile. At Helmsley and Pickering there was a feeling in favour of 1*s.* per mile. He had received private intimation that the committee of the Malton and Norton Boards were making an offer of 2*s.* instead of 1*s.* and 10*s.* instead of 5*s.*, to be inclusive of all claims and to cover what might be termed abortive visits. As far as he could gather this was the most generous offer made hitherto by any board of guardians in England. In the Marylebone Union the fees agreed upon were 2*s.* 6*d.* and 7*s.* 6*d.* In Leyburn the minimum fee was suggested with 1*s.* mileage; Middlesbrough was quite in accord with this meeting, as also was Easingwold.

A debate followed, in the course of which it was freely stated that the 5*s.* fee for successful vaccination at home was too small, that the 1*s.* fee for the statutory visit was ridiculous, and that some system of payment by mileage was the only fair one. Mr. SPRENT moved the following resolution:—

That the fees of public vaccinators should be 2*s.* 6*d.* and 5*s.* in urban districts and 2*s.* 6*d.* and 10*s.* 6*d.* in the rural districts, these fees to cover all duties.

He thought in this way a settlement could be arrived at. In rural districts the loss on long journeys would be equalised by the cases nearer home.

The motion was seconded by Dr. GRAMSHAW and carried unanimously.

PUBLIC VACCINATORS AT NANTWICH AND THEIR FEES.

At the last fortnightly meeting of the Nantwich Board of Guardians held on Saturday, Nov. 26th, a motion was brought forward to confirm certain minutes of the finance committee, which minutes stated that after hearing Mr. William Thomson and Mr. A. E. Vaughan as a deputation the board decided that the minimum fees under the new Act should be the scale of payment for the public vaccinators of the union.

Mr. THOMSON, who was present, regretted this decision but said that the matter could not be settled by the public vaccinators or by the guardians except by mutual agreement. The public vaccinators would not be satisfied with the report of the finance committee if it were adopted by the board and in that case they would be obliged to bring the matter before the Local Government Board to decide. Among the reasons why the public vaccinators thought that

Digitized by Google

the minimum fees should be enlarged, Mr. Thomson enumerated the following. Public vaccinators, on receiving notice from the vaccination officers of any children who had not been vaccinated or whose parents had not received certificates of exemption from the magistrates, were required within fourteen days on the receipt of such notice to visit the homes of such children and to be prepared to vaccinate them where consent was given. The distance of the districts from the residence of the public vaccinators in the Nantwich Union averaged from four to six miles. His district extended on one side five miles and on the other side four miles. The public vaccinator, after at least twenty-four hours' notice to the parent, was required to visit the home of a child in order to vaccinate the child and the minimum fee for his visit would be 1*s.* according to the report of the finance committee; if sanctioned by the board of guardians and allowed to vaccinate a child he would receive a further fee of 5s. in the case of successful vaccination, but if unsuccessful he would receive nothing for his trouble except the visiting fee of 1*s.* Mr. Thomson then showed that the duties of the public vaccinators would be considerably altered under the new Act, so that it was reasonable to make fresh provision for their remuneration. The Act provided that a payment should be made of "not less" than 1*s.* for the visit and of "not less" than 5*s.* in respect of every primary successful vaccination or revaccination performed at the home of the person vaccinated. Only the minimum amount of each of the payments was fixed and, subject to this minimum, the precise sums to be paid might be settled by agreement between the guardians and the public vaccinators, to be approved by the Local Government Board. The inference was obvious, that whilst the minimum payments might be sufficient for small thickly populated districts they were not sufficient for large rural districts which were thinly inhabited. Hence the proposal that the payments should be increased according to distance.

A debate followed, in the course of which it was proposed to refer the question of the fees to be paid for public vaccination to the finance committee for further consideration. The motion to this effect was, however, lost, 15 votes being recorded against it and only 10 in its favour, the effect of which will be that the matter will now be brought before the Local Government Board by the public vaccinators.

PUBLIC VACCINATORS OF CARDIFF.

On Nov. 12th, it will be recollected, the Cardiff Board of Guardians passed a resolution by a majority of 14 to the following effect: "That the contracts with the present public vaccinators for town districts—viz., Messrs. T. G. Horder, Cardiff district; J. Treharne, Roath district; and John Evans, Canton district—be terminated by Jan. 1st and that a fresh contract be entered into for public vaccination in the town of Cardiff with one medical practitioner who shall devote the whole of his time to his duties under the contract." At a meeting of the board of guardians held on Nov. 26th the Rev. J. R. Buckley moved that this resolution be rescinded, a motion which after some discussion was carried by a majority of 23. Mr. Mildon then gave notice of a motion that the three public vaccinators be appointed for one year only under the new Act and that the whole matter should come up for reconsideration then, so that it is evident that the question has not reached a final settlement.

Without entering at present into the question as to whether it is better for a public vaccinator to be a practitioner who devotes the whole of his time to his vaccination duties or not it is quite evident that to dismiss three hard-working officials, some of whom have served the guardians for twenty years, at only six weeks' notice would have been monstrously unjust and we congratulate the Rev. Mr. Buckley on his success in carrying a motion which makes for fair play. We are glad to see also that a certain personal element in the discussion which at one time seemed likely to lead to unpleasantness was amicably set aside.

THE ROENTGEN SOCIETY.

A CONVERSAZIONE of the above society was held by invitation of the President and Mrs. Charles Mansell-Moullin on Nov. 21st at St Martin's Town-hall, London. There was a large collection of special apparatus and of Roentgen photographs, in the latter of which directions the chief medical interest naturally lay. Many varieties of Coils, Tubes, Localisers, Screens, Fluoroscopes, Stereoscopes, and Radiostereoscopes were to be seen, together with a Complete Hospital Outfit by Mr. Isenthal and an Apparatus for Testing the Grade of Rays by Professor Gladstone. The London Hospital was strongly represented by a complete Portable Outfit for Ward and General Purposes consisting of dark-room, operating-table, and all accessories, under the care of Dr. Hedley. Professor Silvanus Thompson demonstrated the action of the Tesla Oscillator upon Vacuum Tubes destitute of Electrodes. A rapidly alternating electric field was excited between two sheets of metal acting as poles of the oscillator, and any vacuum tube placed within that particular sphere of action exhibited luminous discharges. Professor Pepperdene lent a fine set of apparatus, including Rapid Mercury Breaks and Osmium and Osmium-iridium Tubes. Mr. Webster showed Mr. Herbert Jackson's Original Focus Tube and Mr. Wimshurst, F.R.S., one of his famous influence Machines. Mr. A. C. Swinton displayed a number of Experimental Tubes in which the size of the active point of generation of the rays could be accurately determined by a pin-hole Roentgen camera. Professor Gladstone, F.R.S., showed an apparatus for testing the grade of rays which attracted a good deal of attention. Among well-known makers who exhibited were Messrs. Apps, Watson Baker, Cox, Coxeter, Dean, Fuerst, Paxton, and Watson and Sons. A fine collection of Luminous Tubes was contributed by Messrs. J. F. Vezey, A. Cossar, and Gerard Smith. A feature of considerable attraction was the Wheatstone Stereoscope of Mr. Mackenzie Davidson, who showed thereby with wonderful exactness the position of bullets which had been embedded in bone at Dargai and other objects of interest.

A smaller hall was devoted to screen demonstrations with half-a-dozen large coils, and a side-room served as a screen room for demonstrations confined to medical visitors. The latter proved a great attraction. It was under the care of Mr. Frederick Fenton and Dr. Walsh, who showed several cases sent from the London Hospital, one a Wired Resection of the Elbow-joint and another a Congenital Absence of the Clavicles. On the whole it may be said that during the twelve months which have elapsed since the last conversazione of the society no great novelty has been introduced into the technique of Roentgen methods. At the same time the general standard of excellence has greatly advanced, especially in the definition of photographs—in other words, the conditions of exposure are becoming better known to individual workers. Of the many hundreds of photographs shown it will be possible to mention only a few of special excellence. Mr. J. H. Gardiner sent a collection of Radiographs of new and rare fishes from the interior of Africa showing the practical use of the rays in zoology. A good collection came from the London Hospital, taken by Mr. E. Harnack and Dr. Hedley. A number of surgical injuries were illustrated, as well as Thoracic Aneurysm, Charcot's Joint Disease, and other medical subjects. One photograph of a Pelvis showed the immensely magnified shadow of a Murphy's button, the large size whereof was due to the fact that when taken it was 6 in. from the sensitive plate and comparatively close to the focus tube. The photograph of Double Absence of Clavicles in a patient (shown in a screen room) was of great interest. Some remarkable Radiographs of Pelvic and other Bones from the Voltohm Company of Münich pointed to great future possibilities of the method. Mr. Ernest Payne contributed various fractures and diseases of bone, some of them displaying osseous texture with great clearness. Mr. Mackenzie Davidson sent some illustrations of his method of photographing renal calculus by fixing the abdomen. Mr. F. H Glew showed some excellent work, but in one case the close approach of the tube to a shoulder caused the record of the bones to have a magnified and somewhat distorted look. Mr. Poland exhibited a series of Injuries to Epiphyses, a good Ankylosed Knee, in which the direction of new cancellous lamellæ could be clearly traced, and a fine picture of a False Joint after Excision of the Hip. Dr. Hugh Walsham sent a number of Photographs of Pneumonia, Phthisis, Aneurysm, and other Morbid Conditions of the Chest. One of collapsed lung would repay careful study by the medical worker in the x rays. In another the lungs were shown to be clear and the diagnosis of phthisis suggested by the presence of a cough or by advanced disease in a brother was therefore dismissed. A great deal remains to be done in this field of medical diagnosis. Dr. Walsh showed a Hæmophilic Knee-joint in which the bones were enlarged and the whole joint was obscure when contrasted with the sound

Digitized by Google

side. He also showed a Child's Thorax with Seven Ribs Fractured (healed), and Dr. G. Carpenter's case of Absent Clavicles in a child, aged eight years, a rare condition which happily compared with Dr. Schorstein's in the London Hospital exhibit. Dr. F. H. Low had some excellent examples, including one of the few cases of Renal Calculus located by a Radiograph. Mr. Frederick Fenton exhibited a fine collection for Mr. Montague. They included various plates of a Coin in its passage through the Alimentary Canal; Fractured Olecranon fixed by a Screw; two Renal Calculi (excellent); and a Patella the day before and the day after fracture. A most extensive set of Photographs illustrating almost every medical and surgical application of the rays came from Messrs. Allen and Hanburys. Mr. Noble Smith sent some good orthopædic subjects, including a full-length figure of Spinal Curvature built up in segments. Mr. Griffith Wilkin contributed a series showing how criminals might be identified by means of accurate measurements of bone made with the rays. Mr. Prosper Marsden had a good picture of a nine months Fœtus, and Mr. F. Glew one of another of five months. Other good pictures came from Dr. E. L. Mansel, Dr. G. M. Lowe (Lincoln), Mr. H. Coxeter, Dr. Wolfenden, Mr. Thomas Moore (hon. treasurer), Mr. Hall-Edwards, Mr. D. Boyd Keown, Dr. E. Greville, Dr. M. Barbour, and others. From the standpoint of pure artistic photography the honours were easily carried off by Messrs. Webster and Wilson Noble. The President may be congratulated on having brought together the finest collection of Roentgen photographs yet seen in this country.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5632 births and 3748 deaths were registered during the week ending Nov. 26th. The annual rate of mortality in these towns, which had been 17·3 and 17·1 per 1000 in the two preceding weeks, rose again to 17·4 last week. In London the rate was 16·7 per 1000, while it averaged 17·9 in the thirty-two provincial towns. The lowest rates in these towns were 11·3 in Croydon, 12 2 in Huddersfield, 12·3 in Cardiff, and 12·6 in Plymouth; the highest rates were 21·6 in Gateshead, 22·3 in Liverpool, 24·9 in Derby, and 26·1 in Wolverhampton. The 3748 deaths included 364 which were referred to the principal zymotic diseases, against 412 and 371 in the two preceding weeks; of these 83 resulted from measles, 82 from "fever" (principally enteric), 81 from diphtheria, 51 from whooping-cough, 48 from diarrhœa, and 19 from scarlet fever. No death from any of these diseases was recorded last week in Birkenhead; in the other towns they caused the lowest death-rates in Croydon, Burnley, Huddersfield, and Bradford, and the highest rates in Manchester, Liverpool, Sheffield, Halifax, and Swansea. The greatest mortality from measles occurred in West Ham and Manchester; from whooping-cough in Cardiff, Derby, and Gateshead; and from "fever" in Halifax and Sheffield. The mortality from scarlet fever showed no marked excess in any of the large towns. The 81 deaths from diphtheria included 38 in London, 10 in Leeds, 7 in Liverpool, 6 in Sheffield, 4 in Leicester, 3 in Portsmouth, and 3 in Swansea. No fatal case of small-pox was registered during the week under notice, either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 3162, against numbers increasing from 2178 to 3259 at the end of the thirteen preceding weeks; 234 new cases were admitted during the week, against 318, 340, and 319 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 248 and 285 in the two preceding weeks, declined again last week to 280, and were 145 below the corrected average. The causes of 55, or 1·5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Manchester, Newcastle-upon-Tyne, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Liverpool, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 18·9 to 19·5 per 1000, further rose to 19·7 during the week ending Nov. 26th, and exceeded by 2·3 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11·9 in Perth and 15·2 in Paisley to 21·3 in Edinburgh and 22·6 in Aberdeen. The 595 deaths in these towns included 25 which were referred to diarrhœa, 19 to whooping-cough, 11 to "fever" (principally enteric), 10 to measles, 5 to diphtheria, and 3 to scarlet fever. In all, 73 deaths resulted from these principal zymotic diseases, against 86 and 70 in the two preceding weeks. These 73 deaths were equal to an annual rate of 2·4 per 1000, which was 0·7 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 11 and 9 in the two preceding weeks, rose again to 19 last week, of which 12 occurred in Glasgow, 3 in Edinburgh, and 3 in Dundee. The deaths referred to different forms of "fever," which had declined from 18 to 14 in the three preceding weeks, further fell to 11 last week, of which 7 were recorded in Glasgow and 2 in Edinburgh. The 10 fatal cases of measles exceeded by 4 the number in the preceding week, and included 4 in Glasgow and 4 in Edinburgh. The deaths from diphtheria, which had been 11 in each of the two preceding weeks, declined to 5 last week, of which 3 occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 129 and 130 in the two preceding weeks, were 128 last week, and slightly exceeded the number in the corresponding period of last year. The causes of 39, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 30·0 and 27·7 per 1000 in the two preceding weeks, rose again to 31·0 during the week ending Nov. 26th. During the past four weeks the death-rate in the city has averaged 28·4 per 1000, the rate during the same period being 16·4 in London and 20·0 in Edinburgh. The 208 deaths registered in Dublin during the week under notice showed an increase of 22 upon the number in the preceding week, and included 17 which were referred to the principal zymotic diseases, against 22 and 9 in the two preceding weeks; of these, 6 resulted from diarrhœa, 5 from whooping-cough, 4 from scarlet fever, 2 from "fever," and not one either from small-pox, measles, or diphtheria. These 17 deaths were equal to an annual rate of 2·5 per 1000, the zymotic death-rate during the same period being 1·4 in London and 2·3 in Edinburgh. The deaths from whooping-cough, which had been 4 and 2 in the two preceding weeks, rose again to 5 last week. The 4 fatal cases of scarlet fever exceeded the number recorded in any week since April last. The deaths referred to different forms of "fever," which had been 5 and 4 in the two preceding weeks, further declined to 2 last week. The 208 deaths in Dublin last week included 29 of infants under one year of age and 62 of persons aged upwards of sixty years; the deaths of infants showed a marked further decline, while the deaths of elderly persons considerably exceeded those recorded in any recent week. Ten inquest cases and 7 deaths from violence were registered; and 76, or more than a third, of the deaths occurred in public institutions. The causes of 5, or more than 2 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

STAFF-SURGEON ALFRED HENRY MILLER has been promoted to the rank of Fleet-Surgeon in Her Majesty's Fleet. The following qualified candidates for the Naval Medical Service have been appointed Surgeons in Her Majesty's Fleet:—John Boyan, William Henry Daw, Cyril Shepherd, Hugh Leigh Norris, Adrien Andrew Forrester, James Midleton Graham Swainson, John Stoddart, James Aquilon Forrest, Warren Guy Westcott, Francis John McKenna, Fairman Rackham Mann, William Wallace Keir, Edward Charles Sawdy, Percy Hooper Bannister, Richard Sidney

Digitized by Google

Osborne, Mervyn Winfred Falkner, Edward Oliver Bamford Carbery, John Kimber Raymond, and Henry William Melville Lees.

The following appointments are announced:—Fleet-Surgeon Henry W. D. Walsh to the *Sans Pareil*. Staff-Surgeon Robert Hickson to the *Rupert*. Surgeons: Edward Haines to the *Camperdown;* Henry R. Gardner to the *Victory*, for Haslar Hospital; George A. S. Bell to the *Victory*, additional for the *Duke of Wellington;* Herbert H. Pearse to the *Defiance;* and Walter H. S. Stalkart to the *Vernon*. Surgeon and Agent: Charles J. Bernard at Skegness.

ROYAL ARMY MEDICAL CORPS.

Major Thompson embarks for Bombay. Major Hall takes over charge of the Station Hospital, Lydd. Lieutenants Mainprise and McCarthy are posted to Western Heights, Dover, for duty. Major Culling takes over charge of the Station Hospital, Western Heights, Dover, from Major Forman. Majors Woods and Matthias are proceeding to Malta in the transport *Jelunga*. Lieutenant Cowan is posted to the Station Hospital, Belfast, for duty. Major Dorman and Lieutenant Carter embark for service in India shortly.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Captain (temporary) Major Hardy, 2nd Infantry, Hyderabad Contingent, are placed temporarily at the disposal of the Government of Bombay for employment on plague duty. The services of Captain Lumann are placed temporarily at the disposal of the Foreign Department for employment on plague duty in Mysore. The services of Captain Close (Bengal) are replaced at the disposal of the North-Western Provinces and Oudh. The services of Major French (Bengal) are placed temporarily at the disposal of the Government of the North-Western Provinces and Oudh. Lieutenant-Colonel Murray (Bengal) is confirmed in the appointment of Professor of Surgery, Medical College, Calcutta, and *ex-officio* Surgeon to the College Hospital.

THE FEBRUARY COMPETITIVE EXAMINATION FOR THE ROYAL ARMY MEDICAL CORPS.

There will be 24 commissions to be competed for at the next examination for the Royal Army Medical Corps in February next, and we think that the young medical men who are physically fit for medical service, especially such of them as have a taste for travel and a military life, might do well to turn their attention to the advantages which that service offers. In the first place, the pay is regular and sufficient, with reasonable economy, to live upon; a medical officer has the society of officers and gentlemen, and if he is a cultured and agreeable man and fond of his profession he will be heartily welcomed and trusted and make many and lasting friendships; with ordinary care and attention he is sure of promotion and pension on retirement, and with energy, ability, and fair luck he will probably have opportunities for distinction and every chance of being selected for promotion to the upper ranks. As we have previously stated, it is only right and fair to say that Lord Lansdowne has done his best to put the Army Medical Service on a good footing and has, as far as is practicable and present circumstances admit, fulfilled the requirements of medical officers. Under these circumstances we are consequently of opinion that the newly instituted Royal Army Medical Corps merits the attention of young medical graduates and qualified men, and intending candidates would do well to make themselves acquainted beforehand with the regulations as to the physical and professional qualifications required.

THE ARMY MEDICAL RESERVE.

In the opinion of Surgeon-General J. B. Hamilton, the Army Medical Reserve "is a mere paper army, a mockery, a delusion, and a sham." This is plain speaking with a vengeance, but it is impossible to deny that there are grounds for the indictment. As at present constituted the Army Medical Reserve would not be of much use in a national emergency. Military medical work has to be learnt practically under good and experienced teachers. An untrained medical man would at first be more or less of an encumbrance in the field. Whilst he was engaged in learning his duty the force would suffer. No doubt the War Office authorities are perfectly well aware of what is required and will take the necessary steps to set matters right, but now that the needs of the Royal Army Medical Corps have been attended to it would be well if they were to exhibit a little extra energy in dealing with the Army Medical Reserve. It is not too much to say that under existing circumstances it would be impossible for the medical department of the Army to act efficiently in a considerable campaign such as lately seemed to be within a measurable distance.

THE VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

Lieutenant-General Sir George White, V.C., G.C.B., G.C.S.I., &c., Quartermaster-General to the Forces, will present the prizes to the members of the Volunteer Ambulance School of Instruction at St. Martin's Town Hall, Charing-cross, on Wednesday, Dec. 14th, when there will be the usual ladies' night. A large number of the ommanding officers of the Yeomanry and Volunteer Corps of the Home District have expressed their intention of being present. In addition to Sir George White, Lieutenant-General G. H. Moncrieff, Surgeon-General W. Taylor, C.B. (recently Principal Medical Officer to the Khartoum Expedition), Colonel V. Hatton, C.B., and the officers of the 1st Battalion the Grenadier Guards will be the guests of the school. Application for tickets for the Bohemian entertainment should be made to the Mess President, 8, Portman-street, W.

THE TITLES OF RETIRED MEDICAL OFFICERS.

There seems to be a general desire that the new titles conferred by the recent warrant for the constitution of the Royal Army Medical Corps should not be simply restricted to those retired medical officers who are liable to recall, but extended to all medical officers who retired when the compound titles were in force. With a view to the simplification of the titular nomenclature employed and to the inclusion, as far as practicable, of medical officers in one and the same corps—that of the Royal Army Medical Corps—the desire seems to be a reasonable one under the circumstances.

ARMY MEDICAL SERVICE VACANCIES IN DECEMBER.

Surgeon-General A. A. Gore vacates the appointment of Surgeon-General of Her Majesty's Forces and Principal Medical Officer in India. As already announced in THE LANCET Surgeon-General Gore will be succeeded in his appointment by Surgeon-General Taylor, C.B. Colonel F. B. Scott, R.A.M.C., M.D.Glasg., C.M.G., retires on Dec. 9th.

THE QUEEN AND THE WOUNDED SOLDIERS FROM THE SOUDAN.

It is stated that the Queen intends to visit Netley Hospital to-morrow (Saturday) to personally inquire into the cases of the wounded from the Soudan. The visit will be a private one and Her Majesty is expected to arrive at Netley by special train from Windsor at 3 P.M.

DEATHS IN THE SERVICES.

Surgeon-General A. Smith, C.B., honorary physician to the Queen, aged seventy-four years, at his residence, South Kensington, on Nov. 25th.

Correspondence.

"Audi alteram partem."

"FEES TO PUBLIC VACCINATORS."

To the Editors of THE LANCET.

SIRS,—I doubt whether it is fully realised yet what are the duties demanded from public vaccinators under the so-called birth registration fee which has been fixed at a minimum of 1*s.* by the Local Government Board. The wording of this provision is misleading at first sight. It is in no way analogous to the birth registration fee allowed to vaccination officers and is by the various exceptions reduced to such cases only as come under the care of the public vaccinator. For this fee let us see what will be required of us. It will entail at least three, and probably more, of the following duties. 1. Notice of visit and postage. 2. Visit by appointment offering vaccination. 3. Examination of child as to health, the presence of fever, disturbed bowels, and eruptions on any part of body being especially noticed. 4. Postponement certificate to vaccination officer and postage. 5. Inquiry regarding recent exposure to infectious diseases, or prevalence of erysipelas in neighbourhood. 6. Postponement

Digitized by Google

certificate of such cases to vaccination officer and postage. 7. Notice to medical officer of health *re* existence of such and postage. 8. Examination of sanitary state of house, the complete duties of an inspector of nuisances thus devolving on us. 9. Postponement certificate to vaccination officer if insanitary state exists and postage. 10. Certificate (Form P.) to medical officer of health and postage. 11. Indefinite number of visits and certificates of postponement from any of above causes and postage thereof. [This is clearly intended by the title of the fee indicating that only one such fee is recoverable for each birth registered and by the wording of clause (2) in first schedule "Form of vaccination contract"—viz., "and if his offer is accepted the public vaccinator will thereupon *(or after such postponement if any as may in his opinion be necessary)* so vaccinate the child."] 12. Notice to vaccination officer of refusal of parents to allow vaccination and postage. 13. In case of insusceptibility 3 or 4 visits and 2 or 3 operations under aseptic precaution. 14. Certificate of insusceptibility to vaccination officer and postage. 15. Record in register of each unsuccessful operation.

Here, then, is what is involved in that innocent-looking item under birth registration fee, the minimum fee of which is 1*s*. I have also drawn out a list of possible duties required under the vaccination fee, but will not trouble you with the details. One which does not appear to be an improbable issue in these days is that of our having to meet an action lying against us for evil consequences resulting from real or supposed neglect in the performance of the operation or in the examination of the sanitary state of the house previously to our having vaccinated the child.

I am, Sirs, yours faithfully,

F. LORIMER HART,
Public Vaccinator for Lewisham.

Sydenham, S.E., Nov. 26th, 1898.

To the Editors of THE LANCET.

SIRS,—In reply to "Public Vaccinator's" letter in THE LANCET of Nov. 26th may I be allowed to say that the public vaccinators of the Bootle Union, Cumberland, met the guardians last Saturday. We had agreed beforehand to ask 1*s*. a mile over one mile and that this should be paid whether the child was vaccinated or not. I was called before the guardians first to put our wishes before them. After talking the question over for some time I was asked to leave the room and when called in again I was informed that they would only pay for successful vaccination and not mileage, as the Local Government Board would not allow any other arrangement, the clerk especially being very strong on the difficulty of checking the mileage and the disputes which it would cause. They then offered me 5*s*. per case for the urban portion of my district—size, 1311 acres; births, 1898, 356. For the rural portion—population, 1891, 2072, extending about five miles one way and eight miles the other, 11*s*.; for an outlying portion, about twelve to twenty miles from my house, population 279, 25*s*. I accepted this with the understanding that I might apply again in a year or two, and finding I could not get mileage from the urban district. Dr. Cass of Ravenglass, a small village, whose district runs about twelve miles—population in 1891, 2198—got 12*s*. 6*d*. per case; Dr. Hudson of Bootle, a similar village, with the workhouse, and extending about eight miles, with a population in 1891 of 1453, got 9*s*. 6*d*. per case, the registration fee of 1*s*. in all cases to be extra. I hope this information will be of some use to other public vaccinators, and if I can give them any further information I shall be glad to do so by letter or through THE LANCET, with your permission. I should like to have your opinion on the terms we obtained.

I am, Sirs, yours faithfully,

P. BUTLER STONEY,
Public Vaccinator, Millom District, Bootle Union, Cumberland.

Nov. 28th, 1898.

"A CASE OF DEATH FROM DIABETES MELLITUS, IN WHICH THAT DISEASE GAVE NO PREMONITORY SYMPTOMS."

To the Editors of THE LANCET.

SIRS,—A case is recorded in THE LANCET of Nov. 26th under the above heading which, I think, requires a passing word. As it stands it is calculated to give rise to disquietude of a somewhat grave nature. A woman, aged sixty-eight years, in a previously good state of health, suddenly fell down in a comatose condition, which persisted till death twenty-six hours afterwards. The urine and fæces were voided at the commencement of the attack and no urine was at first obtainable for examination. About twelve hours later urine was drawn off by catheter and found to be of specific gravity 1023 and to contain a slight trace of albumin and 16 per 1000 of sugar. From this it is concluded, notwithstanding the total absence of any symptom of diabetes previously, that the attack consisted, not of an apoplectic seizure, but of diabetic coma. The proposition to be confronted is that a person may go about without manifesting the slightest symptomatic indication of the existence of diabetes and then suddenly fall down in a state of profound coma rapidly passing on to a fatal termination. I venture to think that if urine had been obtainable at the commencement it would have been found to be free from sugar. The urine which was examined agreed with that of transient glycosuria instead of with that of true diabetes, and such glycosuria is a well-known accompaniment of an apoplectic seizure.

I am, Sirs, yours faithfully,

Grosvenor-street, W., Nov. 30th, 1898. F. W. PAVY.

THE "PRIVATE SURGEON."

To the Editors of THE LANCET.

SIRS,—Might I be allowed to suggest to the executives of the various "medical defence societies" that it is their duty when a person is charged with a criminal offence and describes himself as a medical man without a legal right to such a dignity to immediately correct these misstatements in the daily press? The frequency of such incidents is calculated to bring discredit on our profession.

I am, Sirs, yours faithfully,

HENRY DUTCH, M.D. BRUX., M.R.C.S. ENG.

Berkeley-street, W., Nov. 27th, 1898.

*** We have lately read the amusing details of a complicated case of roguery said by nearly all the lay accounts to have been committed by a "private surgeon." This is exactly a case in point.—ED. L.

"THE DIPLOMA IN SANITARY SCIENCE OF THE ROYAL UNIVERSITY OF IRELAND."

To the Editors of THE LANCET.

SIRS,—Every graduate or licentiate of the Irish universities or licensing bodies must sympathise with Dr. C. L. Birmingham and Dr. J. E. O'Connor in their objection to the style and title of the sanitary science diploma in the Royal University of Ireland. Surely by a "Diplomate in Sanitary Science" the general public would understand a sanitary inspector who was, perhaps, also a registered plumber or had got a certificate in—if I may use the expression—"hygienic first aid." A year ago the committee of the Conjoint Irish Colleges of Physicians and Surgeons changed the style and title of their "Diploma in State Medicine" to that of "Diploma in Public Health and State Medicine," and in the case of the Royal University of Ireland a similar step ought to be executed with equal facility. The examination for the Diploma in Public Health formerly held by the Royal College of Surgeons in Ireland is now replaced by that held by the Conjoint Colleges of Physicians and Surgeons and is certainly of an average standard with the majority of the Public Health examinations of the United Kingdom.

I am, Sirs, yours faithfully,

MAURICE MCELLIGOTT, L.R.C.P. & S. Irel.,
D.P.H. (Irish Conjoint).

Belper, Nov. 28th, 1898.

To the Editors of THE LANCET.

SIRS,—Dr. J. E. O'Connor is in error when he states in THE LANCET of Nov. 26th that "the Royal College of Surgeons is the only body in Ireland granting a D.P.H." For many years the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland have each granted such diplomas, and about eight years ago these two Colleges united in conferring a conjoint diploma in State medicine which appears to stand well in public estimation if we may judge

Digitized by Google

by the number of applicants who present themselves, notwithstanding a very severe standard of examination. The University of Dublin also has for many years granted a similar diploma which has a very high reputation.

I am, Sirs, yours faithfully.

F. J. B. QUINLAN.

Lower Fitzwilliam-street, Dublin, Nov. 28th, 1898.

"THE STATE SERVICE IN ST. PAUL'S CATHEDRAL."

To the Editors of THE LANCET.

SIRS,—Your correspondent, Dr. Angus Campbell,[1] is troubled in his mind that he sees that bugbear of the medical profession "Advertisement" stalking at large at the yearly service of the Guild of St. Luke. Is it not time that someone asked the question, Why should medical men be so hypersensitive as to taboo any mention of their brethren in the public press? Can anything be more absurd to suppose that our profession is "lowered in the eyes of the intelligent" because a large number of medical men attend the service in state at St. Paul's? Where is the mysterious law written that is supposed to decree that medical men are to shun all publicity and live in seclusion, only to appear if accident discovers them? Why should not your correspondent also attack the guests at the Lord Mayor's banquet to the medical profession for "advertising," because their names appeared in the daily press? Is the Harveian lecturer guilty of "advertisement" because his name is quoted in the newspapers? Is the physician who speaks on some social subject at a public meeting "advertising" because the press report his remarks and do not ignore his name? The fact is there is a growing general interest in medical matters, and as a consequence in medical men. The public press therefore supplies any medical news that is likely to interest readers. I fail to see any cause for regret in this growing interest, but regard it rather as a subject for congratulation. If a surgeon performs successfully some new operation, why should not humanity be at once informed and the fortunate operator be publicly accorded the credit which is due to him? Why should acknowledgment be delayed as long as possible? Why should it be considered unfair to others that he should immediately gain thereby?

Not long ago we had the spectacle of a well-known politician accused of the infamy (?) of "advertising" because he mentioned in an interview that he was also a medical man and showed how hard he worked to do his double duty. Could anything be more preposterous than to accuse such a man of "advertising"? The question of signing bulletins is another point which has attracted adverse criticism. On what grounds does anyone object to the appended names? If the fact be an advertisement why should it be begrudged to those concerned by others less fortunate? Dr. Angus Campbell quotes the Scriptures against the Guild of St. Luke. Let its members retort with equal appropriateness from the gospel of their Patron Saint: "No man when he hath lighted a candle putteth it in a secret place, neither under a bushel, but on a candlestick, that they which come in may see the light."

I am, Sirs, yours faithfully,

Nov. 25th, 1898. FREDERIC VICARS, M.D. Brux.

"GOUT; ITS PATHOLOGY AND TREATMENT."

To the Editors of THE LANCET.

SIRS,—I should not ordinarily venture to make any comment on the extremely kind review of my book on "Gout; its Pathology and Treatment," published in your issue of Nov. 26th, were it not that in the interests of my professional brethren as well as of individuals suffering from gout I think it desirable to call attention to a sentence the context of which is not made quite clear in the review. In referring to the treatment of gout as dealt with in my book the reviewer states that "a mixture of 30 gr. of chloride of ammonium and 15 minims of dilute nitro-hydrochloric acid is also advisable." I think the inference drawn by a reader of the review would be that this is the treatment, or part of the treatment, of acute, subacute, or chronic gout as advised by me. Such, however, is not the case. The clause referred to is taken from p. 220 of the book and a reference to that page will show that such a medicine is specifically advised as part of the treatment of gouty glycosuria and gouty diabetes. I should not think of advising the use of such a mixture in the treatment of acute or subacute gout.

I am, Sirs, yours faithfully,

Weymouth-street, W., Nov. 28th, 1898. ARTHUR P. LUFF.

[1] THE LANCET, Nov. 12th, 1898, p. 1293.

"INJECTION OF SALINE SOLUTION IN SHOCK."

To the Editors of THE LANCET.

SIRS,—In my article on this subject published in THE LANCET of Nov. 26th, at the foot of the first column of page 1390 there occurs an error due to an oversight when correcting the proof. I appear as stating that "a teaspoonful of common salt to a pint of water makes 1 in 875"; it should have been 6 in 875, which is near enough to 6 in 1000 for all practical purposes.

I am, Sirs, yours faithfully,

Liverpool, Nov. 29th, 1898. W. THELWALL THOMAS.

THE CONSCIENTIOUS OBJECTOR.

To the Editors of THE LANCET.

SIRS,—May I suggest that magistrates should have some uniform tabulated list of questions for the above—something like the following, for instance: 1. How many cases and what authorities have you read on the subject? 2. How many cases of vaccination have you seen? 3. How many cases of small-pox have you seen? 4. On what ground have you formed your objections? 5. As you are such a conscientious man, have you any regard for the feelings of your neighbours who on good ground differ from you in opinion and have equally strong conscientious objections to small-pox? 6. Do you plead ignorance or obstinacy? The magistrates may thus possibly be able to satisfy themselves as to the conscience of the objector.

I am, Sirs, yours faithfully,

W. WOODWARD, M.D. St. And.,
Late Public Vaccinator to Worcester District.

Worcester, Nov. 11th, 1898.

"VITALITY."

To the Editors of THE LANCET.

SIRS,—Dr. Beale says: "It would not be profitable just now to discuss what happened many millions of years ago," but as the question is, Can life proceed from non-living matter and forces? and as there was a time when this earth consisted of these only, one would like to know how Dr. Beale explains the first appearance of life upon it. Believers in abiogenesis give an explanation, whatever it may be worth; Dr. Beale gives none. One hopes that what at present is merely a belief may some day, by experiments similar to Dr. Bastian's, become a demonstrable truth; but until living things have been produced from non-living in the laboratory abiogenesis must remain a pure matter of *belief* and quite outside physiology—like belief in a resurrection of the body and a future life. All we can assert at present is that, however life and mind may have originated, we know them only as associated with matter and cannot conceive them as separate and independent.

Dr. Beale asserts that growth or increase in living things is always by addition to their centres, in non-living things to their superficies, so that the latest deposit is always innermost in the former and outermost in the latter, or, as we may say, growth is endogenous and exogenous respectively. But in such living things as trees we find one mode of growth or increase in endogens and the opposite in exogens. He also says: "There is no analogy between growth by aggregation or accretion and growth in living things." In the growth of Mount Vesuvius and that of an oak tree I see a great similarity; in the former the molten lava rises from base to apex, flows over the crater and down the mountain, giving it a new layer; in the oak tree the sap rises from base to apices and streams down its branches and stem, adding a new ring of wood every year to the outside of that of the previous year. Lastly, Dr. Beale

Digitized by Google

says that the term evolution "must be restricted to the living world"; but would geologists, astronomers, and chemists admit this? could they not point to many evolutions of non-living things? and what is this earth of ours to-day but one vast evolution from chaos into cosmos?

I am, Sirs, yours faithfully,

D. HOOPER, M.B. Lond.

Trinity-square, S.E., Nov. 27th, 1898.

THE GENERAL MEDICAL COUNCIL: A CORRECTION.

To the Editors of THE LANCET.

SIRS,—In your report in last week's issue of one of the inquiries heard before the General Medical Council it is stated that I said "that the practice [of the Council] had been ever to consider the neglect of patients, and neglect of patients came within Section 29 of the Medical Act." This is an error. My statement was to the contrary effect. What I stated to the General Council was that in my experience neglect of patients had *never* been considered by the Council as a subject matter of inquiry under the disciplinary jurisdiction established by Section 29 of the Medical Act, 1858. The point is an important one, and I venture therefore to ask you to insert this correction.

I am, Sirs, yours faithfully,

Temple, E.C., Nov. 28th, 1898. M. MUIR MACKENZIE.

THE WORKMEN'S COMPENSATION ACT AND CERTIFICATES FROM HOSPITALS.

To the Editors of THE LANCET.

SIRS,—The Board of Management of this hospital have desired me to inform you, as a matter of possible interest to your readers, that in reference to the new Workmen's Compensation Act they have, in accordance with the recommendation of the honorary medical staff, passed the following provisional resolution: "That a fee of 10*s.* 6*d.* be charged for filling up certificates in connexion with the new Act, and that for the present the hospital residents be responsible for the certificates and retain the fee."

I am, Sirs, yours faithfully,

POOLE GABBETT,

Nov. 26th, 1898. Secretary, Norfolk and Norwich Hospital.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

To the Editors of THE LANCET.

SIRS,—Will you allow me to draw the attention of all members of the profession to the advertisement relating to the College and Polyclinic in your issue of this week? The College will commence work towards the middle or end of January and the coöperation of all interested in making London the centre for post-graduate teaching of the empire is cordially invited. We have lagged too long behind other countries, but we now hope to make up for lost time.

I am, Sirs, yours faithfully,

c. 1st, 1898. J. FLETCHER LITTLE, M.B., Hon. Sec.

"THE REJECTIONS AT THE EXAMINATIONS FOR THE SERVICES."

To the Editors of THE LANCET.

SIRS,—May I ask why you include Aberdeen University in your list of the bodies whose candidates show a heavy percentage of failures at the above examinations when your own report of the proceedings of the General Medical Council shows that Aberdeen had three candidates and three commissions? I believe that my old *alma mater* has always had a fair amount of success at these examinations.

I am, Sirs, yours faithfully,

Nov. 26th, 1893. M.D. ABERD.

*** Peccavimus.—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Plague Commission.—A Pasteur Institute for Hyderabad.—The Decline in the Plague Epidemic.

THE composition of the Plague Commission as well as the objects for which it is said to have been appointed have given rise to considerable comment. A pertinent question was asked in one of the leading Indian papers, "How was it that in the estimation of the Secretary of State the whole body of the Indian Medical Service were disqualified from taking part into the inquiry into plague in India?" The explanation of this may be that an independent investigation for many reasons is most desirable. It is impossible that officers in the Indian Medical Service could approach the administrative side of the subject with anything like a free hand. Themselves officials, they might be calling in question the dicta of their superiors and advisers of the Government—a position impossible with any safety. What is to be wondered at is that the Indian Government has not long ere this appointed a commission or committee of investigation from the officers of the Indian Medical Service into the scientific aspects of the question. One may legitimately ask whether the appointment of this commission is the reply of the Government to a petition for a Plague Congress asked for by the Bombay Medical and Physical Society. It is known that the idea of the congress was very favourably received by the Government of Bombay, but of course such a congress would have no official weight and the Commission may to a certain extent take the place of it. The objects of the Commission have been previously reported, but the exact scope of the inquiry is not very clearly defined. If the purely scientific and medical aspects of plague are to be worked up then the two civilians are out of place, and there seems no reason why two officers in the Indian Medical Service should not have been appointed in their stead. It is remarkable that the services of the so-called Imperial bacteriologist should not have been utilised. For the post of secretary it might have been anticipated, that someone within the Bombay Presidency, where plague has almost exclusively raged, might have been selected. This officer, however, has been brought from Simla. If, on the other hand, the administrative work of the past is to be considered with a view to better order in the future, then bacteriologists are not required so much as men like Sir Richard Thorne, Dr. Parsons, and others, who are accustomed to deal with the investigation of outbreaks of infectious diseases. For experimental work pure and simple assistance could have been obtained from men in India. All the energies of the service seem to have been spent in disinfection, isolation, segregation, and quarantine, with little or no provision for original investigation. Even prophylactic inoculation has had very little encouragement, and although its value has been shown by late statistics the nature of the fluid used stands practically where it was nearly two years ago. If any spirit for investigation had been fostered we might have had by this time an attenuated culture instead of a mere dose of toxin, or we might perhaps have discovered a vaccine. It is not known how long the protection of prophylactic inoculation lasts and the fluid still remains very far from being properly standardised. Again, the incubation period of plague is still unknown and upon the duration of the infection there are very vague opinions and nothing has been definitely established. Towards the discovery of a curative serum, again, nothing apparently has been done.

The Nizam's Government has sanctioned the immediate construction of a complete and thoroughly equipped Pasteur Institute for Hyderabad. It will adjoin the hospital and medical school and will be available in about six months for patients.

The record of plague for the past week is 5907 cases and 4388 deaths. There has been a great increase at Satara but a decrease elsewhere. In Bombay the cases have declined to 92 and the reported deaths during the past week are only 66. In the Madras Presidency there were 22 seizures and 16 deaths and in the Mysore province 529 seizures and 332 deaths. Inoculation is still being carried on at Dharwar and Bangalore with great popularity and the results are reported to be striking.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Manchester Royal Infirmary.

DISCUSSION as to the future of the Manchester Royal Infirmary is now in full tide. A meeting of the trustees was held on Nov. 24th, under the presidency of Lord Derby, to consider the proposal of the board of management, set forth in a report dated June last, for rebuilding the infirmary on its present site. Mr. E. S. Heywood, chairman of the board, brought forward a motion which was seconded by Sir J. W. Maclure, approving the report and reaffirming the decision as to the rebuilding. An amendment was moved by Sir William Houldsworth referring the report back to the board with a request to them to reopen negotiations with the corporation with a view to the sale of the site on terms advantageous to the institution and ensuring the retention of an accident and out-patient department in the centre of the town. Arguments often heard before, sentiment and old associations—not to be esteemed too lightly—as well as convenience, were urged in favour of rebuilding the infirmary on the present site, although by many it is considered much too cramped even with the addition at great cost of some adjoining land which might possibly be obtained. For it must be remembered that practically the board are debarred from covering any more of the present ground although perhaps legally they might do so as the town insists on the unoccupied land being kept as an open space. In addition to want of room there is in the present position of the infirmary a disadvantage from the constant noise all day and almost all night from the surrounding streets. Sir William Houldsworth said that if it were decided to rebuild the infirmary on the present site the trustees would have to consider very carefully where the funds were to come from, whereas if the entire area were sold they would be provided with a fund for rebuilding elsewhere. Unhappily the trustees are in the Tantalus-like position of possessing a property valued twenty-three years ago at over £770,000 which cannot be utilised so long as the infirmary remains where it is. Some time ago it was proposed to sell part of the area to the corporation for £286,000, so that the streets around might be widened while the building was to be left much as it is at present; but that scheme, extravagant for the town and bad for the infirmary, was wisely abandoned. The idea was to retain the present building as a receiving house and out-patient department, but so large a building as the present one would not be required for that purpose. Putting aside sentiment, it seems to many that on the whole the interests of the infirmary—i.e., of the patients—would be best served by the sale of the whole area which would provide funds for an out-patients' department and a receiving house for emergencies of, say, 50 beds, in a convenient situation in the centre of the town but not on the present site, and also for a well-equipped hospital with a sufficient number of beds—say 500—in one of the suburbs. It would be fortunate for the town if it could obtain the infirmary area, as a site is badly wanted for a free library and art gallery, but the question of cost comes in. The corporation feel rather poor just now, having had to expend large sums of late which have not as yet begun to pay a sufficient return, so that if the infirmary square is to be bought some concession as to price may have to be made, provided only that the principle is maintained on which Sir Wm. Houldsworth thinks the sum ought to be assessed. He thinks it should be adequate to rebuild a larger and a complete infirmary; to provide an accident and out-patient department equipped in the best possible manner in the centre of the city but not on the present site, and to cover the maintenance of the two establishments. His amendment was carried, but a poll of the trustees was asked for by Dr. Renaud and it will be taken at a date not yet fixed, so the matter is still in abeyance. When the infirmary was first built, nearly 150 years ago, it was in the country and there would have been no objection on the part of anyone if it had occupied the whole of the present area. But the town grew up to and amœba-like surrounded it, and now vested rights are claimed for the citizens, which is a little hard on the infirmary. If they want the open space they ought to pay handsomely for it and not mulct the infirmary in costs for a state of things which they themselves have brought about. Should it be decided that negotiations with the corporation shall be renewed and a bargain should be arrived at the future site of the infirmary will become the subject of discussion.

The Danger of Flannelette.

The district coroner and the city coroner have frequently to hold inquests in and around Manchester on children who have died from burns sustained when wearing flannelette. The former held one at Levenshulme on Nov. 26th on the body of a child five years old whose nightdress caught fire. This was the third accident of the same kind investigated by him during the week, the child in each case wearing flannelette. It would perhaps be almost impossible to get the mothers in the humbler classes to adopt any of the modes of rendering flannelette fireproof, but there is no doubt that its widespread use has greatly increased the dangers of childhood.

Agricola on Milk.

A conference in connexion with the Macclesfield and District Chamber of Agriculture was held at Macclesfield on Nov. 26th to consider the clauses relating to the milk-supply and tuberculosis in the Additional Powers Bill of the Manchester Corporation. It was maintained by the chairman that tubercle in Manchester was due to insanitary conditions and not to milk. A resolution was passed unanimously expressing the opinion that the powers sought by the bill were unnecessary and unreasonable, and if put into effect would be harassing, vexatious, and ruinous to the farmer without being beneficial to the public. A second resolution urged that the Government should refuse to grant specific powers to individual corporations and that the subject, if dealt with at all, should be treated on a national basis. In the course of the discussion Dr. Niven's writings were subjected to some severe bucolic criticism which probably will not give that gentleman much uneasiness.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Finances of the Edinburgh Royal Infirmary.

AT the meeting of the board of the Edinburgh Royal Infirmary on Nov. 28th an interim report on the finances of the institution was laid on the table. It showed that the total ordinary income was £30,383, being a decrease of £236 on last year. The extraordinary income, which included donations and legacies of £100 and over, amounted to £21,237, while other extraordinary sums amounting to £59,727 were placed to the credit of the extension fund. The total ordinary expenditure for the year amounted to £41,835, being an increase of £800 over the preceding year. The average daily number of patients was 698. Dealing with extraordinary expenditure, the report stated that the sum amounted to £9185, as compared with £5528 in the previous year, the principal items being as follows: electric lighting, £5793; alterations on theatres, £747; new medical electrical department, £641; and interest to beneficiaries, &c., £734. The year's expenditure on the convalescent home amounted to £2228, as against £2184. The convener of the House Committee in explaining the accounts pointed out that the increase of £800 in expenditure over the previous year had been caused to a very large extent by the increase in wages which amounted to £625. They had expended a larger sum than usual in cleaning and putting the infirmary in order in view of the visit of the British Medical Association to Edinburgh. They had, however, to face the fact that the ordinary expenditure exceeded the ordinary income by £11,502, and this notwithstanding the fact that the infirmary had been carried on most economically. The extraordinary income for the year was £11,032 more than that of the previous year, but he impressed upon the board that this was a very fluctuating source of income. Referring to the total ordinary expenditure he held that the money had been well spent and that the infirmary had been conducted with great economy. During the year there had been on an average every night in the infirmary from 1000 to 1020 people, including patients, nurses, resident physicians and surgeons, and servants. If they compared the expenditure with the 1000 people in the house every night the cost for every person was 2*s.* 3½*d.* and that was not the cost merely of maintenance and feeding but it was the cost of the medical expenditure, which amounted to £4460, of all salaries and wages,

Digitized by Google

of coal, lighting, taxes, and assessments, of outlay on building, furnishing, and of very many other expenses that they had to meet. If all that was taken into consideration the 2*s.* 3½*d.* was a very moderate sum indeed. In addition there were over 30,000 outdoor patients during the year and many of these attended two, three, or four times. He thought they would all agree with him that the infirmary had been economically and carefully managed and that they were indebted to their superintendent, Surgeon-Major-General Lithgow, for the care he had taken in making the money go as far as it possibly could.

Outbreak of Typhus Fever in Edinburgh.

Last week it was reported to the Public Health Committee of the Edinburgh Town Council that an outbreak of typhus fever had occurred in the Simon-square district and that upwards of 30 cases had been received into the City Hospital. It was stated that what had led to the spread of the disease had been the difficulty of recognising its earlier symptoms, the cases having been generally regarded as cases of typhoid fever, scarlet fever, rheumatic fever, and influenza. Six cases had been removed from the infirmary and one from the Deaconesses' Hospital. The exact origin of the outbreak had not been determined with certainty, but everything pointed to a "wake" having been the starting point.

Infectious Diseases in Edinburgh.

At this meeting of the Public Health Committee it was also reported that during the month of October 791 cases of infectious disease had been notified. These included 1 case of typhus fever, 29 of typhoid fever, 29 of diphtheria, 288 of scarlet fever, and 444 of measles. This was the highest number of cases of infectious disease in October for the past six years. There were 400 patients in the City Fever Hospital at the date of the report.

University of Edinburgh: Statistics of the October Examinations.

At the medical preliminary examination the results were as follows:—English, 51 passed, 45 failed; mathematics, 40 passed, 48 failed; Latin, 57 passed, 51 failed; Greek, 16 passed, 5 failed; French, 29 passed, 34 failed; German, 3 passed, 4 failed; Dutch, 1 failed; Armenian, 1 passed; Arabic, 1 passed; Russian, 1 passed. The following statistics show the number of first year students in the Faculty of Medicine: Passed preliminary at one university examination, 27; passed preliminary at two university examinations, 9; passed preliminary partly with outside exemptions, 10; passed preliminary entirely with outside exemptions, 64; exempted by degrees in arts or in science, 9; completed preliminary examination, 119, as against 129 in October, 1897; formerly completed preliminary or otherwise accounted for, 68; total first year students of medicine, 187. The number of female extra-academical graduation students of medicine was 67.

Dinner and Presentation to Dr. James B. Russell.

On the evening of Friday, Nov. 25th, the Society of Medical Officers of Health of Scotland entertained Dr. James B. Russell, the new medical member of the Local Government Board, to dinner in the Windsor Hotel, Glasgow. Dr. Campbell Munro, the President of the society, occupied the chair and Dr. J. C. McVail acted as croupier. After the usual loyal and patriotic toasts Dr. McVail proposed the health of the guest of the evening and spoke in high terms of Dr. Russell's signal services to public health, not merely in his own city of Glasgow but in Scotland generally, and not merely to his sanitary authority but to the public and the medical profession. The President then presented Dr. Russell with an address on parchment contained in a handsome silver casket suitably inscribed. Dr. Russell, in his reply, thanked the members for their good wishes and their beautiful gift, and expressed his great gratification in the knowledge that in entering on his new duties he possessed the friendship and confidence of his colleagues of the public health service.

Glasgow Western Infirmary.

The annual meeting of qualified contributors to the infirmary was held on Nov. 24th. The report referred to the recent improvements introduced in connexion with the infirmary, such as the installation of the electric light, a new dining-hall for the nurses, &c. The projected dispensary for out-patients which is expected to cost about £25,000 will be commenced shortly. A movement in favour of securing the presence of ladies on the board of management found expression at the meeting but was not pushed to a vote, the chairman undertaking on behalf of the managers to give the proposal full consideration.

Glasgow Health Department.

It is intimated that the official proposals for the new arrangements rendered necessary by the appointment of Dr. J. B. Russell to the Local Government Board include the nomination of Dr. A. K. Chalmers as medical officer of health at a salary of £700 per annum and the election of an assistant medical officer at £250 per annum. It is also proposed to confer on Dr. Russell an annuity of £250. The decision on all these points lies with the corporation and if rumour is correct will only be reached after some controversy. Dr. Russell's impending removal to Edinburgh has been utilised for the purpose of expressing appreciation of his work and influence in many quarters.

Curious Action against a Surgeon for Assault.

The medical officer of the prison of Glasgow, Mr. James Devon, is at present the defendant in a very unusual action. The pursuer is an engineer who during his compulsory residence in the prison was in the usual course vaccinated, or rather revaccinated, by the defendant. For this, which he claims was an assault, he now sues the medical officer and places the damage at the sum of £500. He also avers that no proper examination of the vaccine matter was made and that the instrument with which the operation was performed was not clean, having been previously used in the vaccination of other prisoners. The answer to these charges is that whilst revaccination was not compulsory the pursuer consented, or at least did not object, to the operation; that the vaccine matter was pure calf lymph; that there is no ground for the pursuer's statement of uncleanliness; and that the pursuer having suffered no injury is not entitled to compensation. The sheriff has heard witnesses in the case but has not yet given his decision.

The Case of Abraham Eastburn.

Abraham Eastburn who was convicted in the Glasgow Sheriff Court in July last and fined £20 for a contravention of the Medical Act has, as the result of his appeal to the Court of Session, secured the reversal of the conviction. The reasons for this judicial finding were that certain evidence in reference to the Medical Register had been improperly admitted and that the letters A.M.S. which the appellant placed after his name did not correspond to or suggest any registrable medical qualification.

Nov. 29th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin University Biological Association.

THE opening meeting of the Dublin University Biological Association which took place on Nov. 25th was attended by a large number of distinguished visitors who wished to hear the important communication of Dr. Haughton on the Present Position of the Roentgen Rays in Surgery and Medicine. He divided his subject into three portions, discussing, firstly, the cases in which a reasonable amount of success might be confidently expected; next, those in which the results must be judged with a due regard to the difficulties surrounding each; and, lastly, the influence of the Roentgen method of treatment on bacterial diseases and as a therapeutic agent useful in other directions. The lecture was fully illustrated with lantern slides and photographs, the pathological as well as the curative effects of the "rays" being fully dealt with. Mr. Mitchell Banks, of Liverpool, in proposing a vote of thanks to the lecturer mentioned that he had been permitted by the President of the association to exhibit some specimens of his own illustrative of the subject. He then gave a most interesting demonstration of views on the screen of skiagraphs showing various conditions of bone and the presence of different foreign bodies in the flesh, the last photograph shown being that of the hand of Lord Lister. Mr. Banks then gave a most valuable and careful criticism of what had really been done by the Roentgen rays in surgery and

Digitized by Google

medicine and what might still be expected to be performed in the same direction and by improved means. The resolution was seconded by Sir William Stokes in an eloquent speech in which, abandoning all attempts at sceptical criticism, he described himself as a most enthusiastic believer in the good already done and likely still to be done for surgery and medicine by means of the "rays," concluding by the statement that he regarded the discovery as one of the most beneficent gifts that physical science had conferred upon them during his own time. Surgeon-General Preston and Major Battersby, recently the director of the Roentgen operations on the wounded in the Soudan, addressed the meeting.

Annual Dinner of the Ulster Medical Society.

The annual dinner of the Ulster Medical Society was held in Prince's Restaurant, Belfast, on Nov. 24th The President, Dr. Nelson, occupied the chair and over 60 gentlemen sat down to dinner. The following were the toasts:—"The Queen" and "The Prince and Princess of Wales and the other members of the Royal Family," proposed by the President; "The Lord Lieutenant and Prosperity to Ireland," proposed by Mr. Kerin and responded to by Brigade-Surgeon McFarland; "The Queen's College and Belfast Medical School," which was proposed by Dr. King Kerr and to which the President of the College (Dr. Hamilton), Professor Byers, and Dr. Calwell replied; "The British Medical Association," proposed by Dr. Lindsay and responded to by Dr. O'Neill, President of the North of Ireland Branch, and the Secretary, Dr. John Campbell; "The Army, Navy, and Reserve Forces," proposed by Professor Whitla and responded to by Colonel Moore, principal medical officer of the Belfast district. "The President of the Ulster Medical Society" was very happily proposed by his old friend Dr. Walton Browne, who spoke of their long and warm comradeship. Dr. Nelson (the President) having made a very feeling reply, in which he thanked the company for the warm way they had toasted his health, proposed "The Secretary" (Dr. Colville), to whom largely the success of the dinner was due. Dr. Colville made a humorous response. During the evening songs were given by Mr. W. G. Mackenzie and Dr. R. C. McCullagh, Dr. Mulholland playing the accompaniments; and Dr. Morrow recited an amusing piece, "The Motor Car." The dinner was in every way a success.

The Belfast Royal Hospital.

At the annual meeting of the subscribers of the Royal Hospital, held on Nov. 12th, it was reported that there had, during the year ended August 31st, been 2317 new intern cases, which, added to 142 remaining in the hospital from the previous year, make a total of 2459 intern patients treated during the twelve months. Of these, 976 were medical and 1483 surgical. There were 24,455 extern cases, and of these 19,185 were surgical and 3214 medical. The total number of cases (intern and extern) treated at the hospital was 26,914. There were 145 students during the winter and 119 during the summer session. It is interesting to note that though there is an increase of intern and extern cases the daily expenditure per head is not so high as last year, being 2*s.* 2½*d.* The sum of £350 15*s.* 10*d.* (including £10 10*s.* from the Lord Mayor) was received from the Hospital Saturday Committee, being an increase of £83 2*s.* 11*d.* over that of the preceding year. The church collections have been only £366 14*s.* 8*d.*, being £23 less than the preceding year. The working classes contributed £2534 1*s.* 11*d.*, which, with £50 given by the Tramway Company, makes a total of £2584 1*s.* 11*d.*, an increase of £69 0*s.* 10*d.* over last year. The receipts for the year from all sources amounted to £7891 10*s.* 1*d.* and the expenditure £8266 3*s.* 9*d.*, the expenditure thus exceeding the income by £374 13*s.* 8*d.* The year commenced with a debt of £349 1*s.* 11*d.* and ends with a deficit of £2104 12*s.* 11*d.* Special attention was drawn at the meeting to the falling off in the church collections, and it is hoped that the heads of the churches will in the future agree upon some particular day for a Hospital Sunday. A resolution was carried authorising the board of management to sell and dispose of securities representing the funded capital of the hospital, not exceeding £3000, toward meeting the present liabilities of the hospital.—At the quarterly meeting held on Nov. 28th, it having been stated in the report that the debt of the hospital on Oct. 31st was £3228 16*s.*, Mr. Pirrie (one of the partners of Harland and Wolff) made a suggestion, which was warmly received, for increasing the funds of the charity. He said that on Jan. 14th of the coming year the most important event in shipbuilding and marine engineering would take place—the launching from their premises in Queen's Island of the *Oceanic*, the largest and heaviest boat ever yet built or launched, a ship larger than the *Great Eastern* and twice the size of the Ark. This he looked upon as the most important event which had ever taken place in Belfast shipbuilding, and his proposal was that a considerable number of the tickets of admission to the Victoria Wharf (where a seated stand would be erected) should be given to the board of management of the Royal Hospital to dispose of at whatever price they could obtain for them to those who wished to witness the launch. Mr. Ismay, chairman of the White Star Line, had also given his consent to the proposal. A hearty vote of thanks was accorded to Mr. Ismay and Messrs. Harland and Wolff for their generous offer.

The Royal Victoria Hospital, Belfast.

It is understood that the Executive Committee will shortly appoint an architect for the new Royal Victoria Hospital, to be erected on the site given them in the Grosvenor-road, opposite the Dunville-park, by the city corporation.

The Belfast Maternity Hospital.

A sale of work in aid of this charity was opened on Nov. 22nd by the Marchioness of Dufferin and Ava. She hoped they would soon have a new hospital.

Nov. 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Tuberculosis.

THE various methods of treatment suggested for tuberculosis formed the subject of discussion at the meeting of the Society of Biology held on Nov. 12th. MM. Richet and Héricourt communicated a report upon their researches into the action of various substances in tuberculosis. With regard to this matter they have made special researches into the action of turpentine. The drug was administered by inhalation, a method which they found better than injections, for by its use any operation is avoided and the drug is brought into direct contact with the microbes in the lungs and the dose can be carefully graduated until nearly a poisonous dose is reached. The animal experimented upon is placed in a box and made to inhale air charged with the vapour of turpentine in the proportion of 12 grammes of turpentine to 1200 litres of air, this being the quantity which passes through the box in one hour. The animals used underwent this treatment from March 7th to August 2nd for a space of one hour every four or five days. The drug was pushed so far as to sometimes bring on convulsions, but when this happened the animals were removed from the box. Three dogs previously inoculated with human tubercle were treated by this method and only 1 died, whilst out of 200 dogs which were inoculated during a period of eight years with human tubercle and which received no treatment not one lived more than seven months. At the same meeting of the society M. Sabrayés of Bordeaux communicated some results he had obtained as to the treatment of tuberculosis by tannin. Inoculation of a guinea-pig with an emulsion of Koch's bacillus and tannin produced virulent tuberculosis, the tannin having no action whatever when the mixture was injected at once, neither did it have any appreciable action when the emulsion was left *in vitro* for forty-six hours. The bacillus of tubercle is therefore resistant to tannin, and experiments go to show that it possesses equal powers of resistance to gallic acid. However, since it has been shown that tubercle bacilli after being submitted to the action of tannin lose the power of growing in artificial culture media, it is obvious that any experiments upon reputed remedies for tuberculosis ought to be substantiated by tests on a guinea-pig, or else the observer may consider that substances which in reality possess no antitoxic powers are of some service. M. Sabrayés, as the result of his experiments, considers that tannin has not the slightest effect in preventing the progress of tubercle in the guinea-pig, although it does not follow from this that it is equally inefficacious in the case of a human being.

The Fungus Parasite of Cancer.

At the same meeting of the Society of Biology M. Bra made known the results of his researches into the fungus parasite of cancer. For four years he has made cultures

Digitized by Google

from 204 cases of new growth, such as carcinoma of the ovary, cancer of the rectum, carcinoma of the body of the uterus, epithelioma of the tongue, epithelioma of the cervix uteri, carcinoma of the parotid gland, sarcoma of the maxilla, and carcinoma of the breast. From all these cultures M. Bra has been able to isolate without fail a fungus bearing a strong resemblance to the family of the ascomycetes. It appears in the form of round cells which form spherules, which give rise to spores shaped like cylinders which in turn produce hyphæ. The spherules are yellow in colour, round or ovoid, possessing a hyaline membrane, and furnished with a pore through which the spores escape.

New Hospital Buildings.

A new block has been opened at the Hôpital St. Antoine. It is to be devoted to the *clinique médicale* of Professor Hayem. Dr. Brouardel, Dr. Napias, director of the Assistance Publique, and M. Liard, head of the Education Department, have officially taken over the buildings which they have handed over to Professor Hayem who gave an address on the occasion of his receiving them and who also drew up the plans for them. The new block looks on to the large gardens of the hospital. In it is realised the utmost perfection of modern hospital architecture and it possesses a theatre, examination halls, a large chemical laboratory, a laboratory for pathological anatomy, a bacteriological laboratory with three culture stoves and three autoclaves. There are also a lift, a room for electro-therapeutics, and rooms for gynæcology and other subjects. The building is admirably ventilated and lighted. The theatre may be darkened instantaneously for lantern shows and radiographic experiments, and galleries from the wards communicate directly with this theatre, so that patients may be at once transferred when necessary from the one to the other. —The town of Havre has just decided to build a new sanatorium for isolating and treating cases of tuberculosis, in accordance with the report of Dr. Sorel. The sanatorium will be in the form of a villa on the shore, and a committee composed of three members, in addition to M. Sorel, have gone to study the organisation and construction of the sanatoria on the banks of the Rhine.—A new hospital at Tunis has just been opened, and the head physician, Dr. Bari, has been awarded the Legion of Honour.

The late Dr. Grubi.

Dr. Grubi recently died in Paris at the age of eighty-nine years. Although a Hungarian by birth, he came very early in life to Paris, where he devoted himself to laboratory work. His microscopical researches led him amongst other discoveries to that of the special fungus of tinea tonsurans. He then gave up strictly scientific work and devoted himself entirely to his patients, among whom his success was brilliant. He had for patients many of the men of letters of the Second Empire, such as Alexandre Dumas and Heine. He was remarkable for his extraordinary prescriptions which made his *confrères* consider him as somewhat of a charlatan or else as a facile employer of suggestion. For instance, he would frequently prescribe to a patient to live in a room entirely green and to this end to have all the window-panes, the wall-paper, the curtains, and all the furniture entirely new. Sometimes, too, he would order his patients to wear nothing but clothes of a certain colour and a certain cut and only to walk in certain streets and on a certain side of the pavement; the position (*orientation*) of the bed was also rigidly laid down according to his ruling. As he suffered from morbus cordis he gave out a long time ago that he was perfectly determined to die alone and for many months he never quitted his room where he lived practically a prisoner, only being seen by one servant and locking the door whenever this man took his departure. Under these circumstances he died, and the police commissary, called by the servants, forced open the door and found that he had been dead for some days. Before he died he had taken care to blow out the candle.

Nov. 28th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

A New Hypnotic.

A NEW hypnotic, to which the name of "heroïn" has been given, has been tried in the medical clinic of Professor Gerhardt in Berlin. According to a communication made by Dr. Strube to the *Berliner Klinische Wochenschrift* it is a product of the di-acetic ester of morphia, and it was discovered by Professor Dreser, chief of the chemical department of the Elberfeld Farben Fabriken. Large doses given to animals were followed by narcosis attended by disappearance of reflex movements and a diminished rate of respiration. In cats tetanic convulsions developed. Smaller doses reduced the number of respirations in a given time but caused an increase in the respiratory force. No paralysis of the respiratory centre was ever observed and the circulation was unaffected. The action of heroïn is very like that of codeia, but smaller doses of the former are required. It is especially useful in dyspnœa, where a decrease of the number of respirations is indicated. Heroïn is a fine white powder of slightly bitter taste; it is practically insoluble in water but its solubility is increased when a few drops of acetic acid are added. Dr. Strube administered it in cases of pulmonary affection and in tuberculosis in place of morphia and codeia, the dose being ½ centigramme (1/75 grain) given either in pills or in powder or even in the form of drops. The limits of 1 centigramme (⅓ grain) for a dose or 25 centigrammes (3¾ grains) in twenty-four hours were not exceeded. The effect was satisfactory in nearly every instance. The patients had no objection to the remedy; after taking ½ centigramme or 1 centigramme they fell asleep, their dyspnœa was relieved, and the cough was stopped. The action of the drug began in about half an hour and lasted from two to four hours, after which another dose was given the effect of which continued till next morning. In a few instances, however, heroïn proved useless and subcutaneous injections of morphine had to be resorted to. Dr. Strube also tried this substance for the relief of neuralgic pains. In two cases of brachial neuralgia and sciatica respectively a centigramme was injected subcutaneously but proved to be without any effect. No undesirable complications were observed and the respiration continued to be regular, the pulse was strong and full, and the temperature was not influenced.

Long Retention of a Pessary.

A remarkable case was lately under observation in the midwives training school in Strasburg. A woman, aged sixty-five years, came to the out-patients' department there to have a pessary removed which she had worn for five years. The pessary had not been withdrawn for the last two years and a midwife consulted by the patient before coming to the hospital had not been able to dislodge it. Dr. Frank, writing in the *Münchener Medicinische Wochenschrift*, stated that the woman could neither stand nor walk without severe pain. The pessary proved to be as it were imprisoned in the vagina, for it could be rotated but not moved to or fro. When it was pulled with some force there was profuse hæmorrhage from the cicatricial formations which retained it in its position. As these structures bled freely when incised and as the woman was rather weak Dr. Frank endeavoured to subdivide the pessary and remove it piecemeal. It was therefore cut up with a saw into portions which were withdrawn without difficulty and without any serious hæmorrhage. When the vagina was at last cleared it was ascertained that the prolapse for which the pessary had been applied was overcome by the extensive cicatrisation, so that the woman's self-neglect had turned out to her advantage.

The Prophylaxis of Puerperal Fever.

Professor Hofmeier of Würzburg has recommended the prophylactic disinfection of the vagina and cervix uteri at the beginning of labour in order to avoid puerperal complications. He uses for this purpose irrigations with solution of corrosive sublimate. To his already published list of 3000 cases treated in this way he now adds in the *Berliner Klinische Wochenschrift* a new series of 1000 cases treated in the obstetrical clinic of Würzburg. The results obtained by him were excellent. In the last series only 7 women died; there was no case of puerperal infection following normal delivery. In all the 4000 cases already published there were only 6 cases of puerperal infection, of which 4 may have arisen within the hospital. Among the last 1000 cases there were 106 in which the temperature rose to over 38° C. (100·4° F.) during the puerperium; in 50 of these 106 cases the elevation of temperature was not due to puerperal infection but to other causes—especially to mastitis. Among the remaining 56 cases there were 10 in which the temperature rose above 39° C. (102·2° F.) and in 2 cases a severe complication (septic

Digitized by Google

endometritis and purulent phlebitis of the left thigh) developed. The sick-rate of all the 4000 women was 382 = 9·5 per cent.; 235 = 5·9 per cent. of the whole suffered from puerperal infection. Every case where there was a temperature of more than 38° C. during the puerperium, even when no other troubles developed, was registered as abnormal, and when it was more than 39° C. the case was regarded as being seriously complicated. Of the above 235 cases 138 = 3·4 per cent. belonged to the first and 97 = 2·4 per cent. to the second category. These results are, in Professor Hofmeier's opinion, due to the above-mentioned prophylactic disinfection of the genitals. The results are the more remarkable as the hygienic conditions of the Würzburg lying-in hospital are far from being satisfactory. The building is old, the wards are generally overcrowded, and instruction is given on a considerable scale both to students and to apprentice midwives. Other lying-in hospitals, that of Basle in Switzerland, for instance, show a much greater sick rate. Although the obstetrical clinic of that town is quite new and furnished according to modern requirements there were 170 cases of complications in 750 deliveries, being a sick rate of 22 per cent.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Organisation of the Army Medical Corps.

SURGEON-GENERAL STERNBERG makes the following statement:—"The number of medical officers allowed by law is inadequate in times of peace. The full number is 192 and there are at present 13 vacancies. The administration of the Surgeon-General's office and the Army Medical Museum requires 6; 11 are on duty at medical supply depôts and as chief surgeons of military departments; 1 is at the Soldiers' Home; 56 are at general hospitals, on hospital ships, and at garrisoned posts; 4 have been disabled since the commencement of the war by sickness; 5 are on duty as chief surgeons of army corps. This leaves 97 medical officers available for duty with troops on the field; 35 of these have been appointed brigade-surgeons of volunteers and are distributed among the various army corps. Since the declaration of war the loss by death has been 2; and 23 are now absent from duty on sick leave. This deficiency in regular medical officers has made it necessary to employ more than 650 contract surgeons. Besides these there have been appointed by the President 8 corps surgeons with the rank of lieutenant-colonel, 24 division surgeons with the rank of major, 86 brigade surgeons, also 3 medical officers for each of the regiments of the United States infantry, cavalry, and engineers. All voluntary regiments have 3 medical officers appointed by Governors of States." Referring to the alleged deficiency of medical officers with the Fifth Army Corps at Santiago he states that "this corps on leaving Tampa had with it 46 regular medical officers and 25 contract medical men, a total of 71, or over 4 per 1000 of the strength of the command, which was reported about 16,000. Additional medical assistance was sent by the hospital ship *Relief*, which arrived at Siboney on July 7th with 20 medical men on board. There was also some volunteer assistance by Dr. Lesser of the Red Cross Society, Dr. Rudberg of the Swedish navy, and several surgeons of the navy from ships in the vicinity." It was not the expectation of the medical department that every wounded man would receive the attention of a surgeon at once—no modern army makes such provision of medical assistance as this service would require—but attached to our army there is a corps of non-combatants known as the Hospital Corps, which is the organised and authorised Red Cross of the army. At the outbreak of the war we had 1800 hospital corps men in the service; at present there are more than 6000. These men wear a brassard upon the left arm bearing the red cross of the Geneva Convention.

Condemnation of Behring's Patent.

The Mississippi Valley Medical Association has set the seal of its condemnation upon the unethical conduct of Professor Behring and resolved that it is the duty of every member to renounce the use of the Behring serum; also, that the American manufacturers who purpose contesting the patent in the courts are entitled to the moral and substantial support of every American practitioner. It also resolved that an earnest appeal should be made to the members of the Commission on the Revision of our Trade Mark and Patent Laws, appointed by President McKinley, and their assistance invoked for the modification of existing laws and the suppression of prevailing abuses.

The Dry-Air Treatment of Tuberculosis.

The dry-air plan of treating pauper patients afflicted with tuberculosis of the lungs is to be given a trial at the new Charity Hospital, which was opened for the reception of patients at Dunning, near Chicago, on Nov. 1st. This institution is designed to put in practice the dry-air treatment for phthisis, and will accommodate 450 patients. The object is to reproduce as nearly as possible the climate of Arizona and New Mexico. The County Board of Commissioners appropriated $60,000 for this hospital and more recently $3000 more have been set aside to complete the work. Statistics show that one-eleventh of the deaths in Chicago is due to phthisis.

Statistics of Crime in the United States.

At the last meeting of the National Prison Association the President, Mr. Brockway, stated that present statistics show nothing of scientific value as to the increase or decrease of crime in the United States, and there are no accessible data by which a just international comparison of the amount of criminality can possibly be made. It is estimated that the number of convictions for crime of every grade annually in the United States is 720,000; the number of committals to prison is 260,000; and the number of prisoners in all gaols, including the juvenile prisons, is 85,000. A rough estimate is made of the cost of crime in the United States, which includes the expense of police and constabulary courts, trials, witnesses, &c., prison maintenance, and interest on investments for prison establishments, excluding from the calculation the amount of loss from the crimes themselves, and the footings exceed $50,000,000 of annual expenditures.

Nov. 18th.

Obituary.

ALEXANDER SMITH, C.B., M.D., L.R.C.S. EDIN.,

SURGEON-GENERAL ARMY (RETIRED); HONORARY PHYSICIAN TO THE QUEEN.

SURGEON-GENERAL ALEXANDER SMITH, who died on Nov. 25th at his residence in Alfred-place, South Kensington, was one of the numerous military medical officers whose record of service is long and distinguished. He was born about 1824, his parents being residents in Banffshire. Medicine having been selected as his profession he attended the usual classes and became qualified in 1846 as M.D. of Edinburgh University and Licentiate of the Royal College of Surgeons of Edinburgh. In the same year he entered the army as assistant surgeon and was promoted to be surgeon in January, 1855. His first war service was in the Crimea in 1855; he was present at the siege of Sebastopol, including the assault on the Redan on June 18th, and was awarded a medal with clasp and a Turkish medal. In 1866 he became surgeon-major and in April, 1876, he was promoted to be deputy-surgeon-general. In 1877-78 he accompanied the expedition against the Jowaki Afridis and received the medal. In the Afghan War of 1878-80 he was principal medical officer, being present in the engagements at Amed Kheyl and Urzu, near Ghazni. For his services in this campaign he was mentioned in despatches and received the C.B. as well as a medal and clasp. In 1881 he became surgeon-general and he retired in 1884. Surgeon-General Smith was married twice. His death was somewhat sudden. His daughter, however, was with him during his last moments, and at a coroner's inquest held on Nov. 29th the sad event was attributed to syncope.

WILLIAM AUGUSTUS BUCHAN, M.B., C.M. EDIN., L.S.A.

DR. W. A. BUCHAN died at his residence, 8, Crescent-place, Plymouth, on Nov. 26th, from pneumonia, after an illness of only a few days' duration. Dr. Buchan was the son of the late

Digitized by Google

Captain D. A. Buchan, R.N. He received his medical education at Edinburgh University and the London Hospital and took the qualification of L.S.A. in 1881, graduating M.B., C.M. Edin., a year later. He then held the posts of house surgeon first at the Manchester Clinical Hospital for Women and Children and afterwards at the South Devon and East Cornwall Hospital, Plymouth. On resigning the latter appointment about twelve years ago he commenced private practice in Plymouth and soon became a well-known practitioner. He was appointed medical officer for the Provident Branch of the Plymouth Public Dispensary and certifying factory surgeon for the town. The deceased took a great interest in ambulance work and was an examiner for the St. John Ambulance Association. He also took much interest in Church work, being for some years churchwarden at St. Peter's Church and a member of the Guild of St. Luke. Dr. Buchan, who was only thirty-nine years of age at the time of his death, leaves a widow and two sons (one an infant). The news of his premature death has been received in Plymouth with much regret as he was very popular and was held in the highest esteem.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Louis Flatow, a well-known and greatly respected Berlin practitioner, from apoplexy at the age of sixty-four years. He was decorated with the Iron Cross during the Franco-German War, and since he settled in Berlin he had been indefatigable in his efforts to raise the position of the medical profession.—Dr. Turel, Professor of External Pathology in the Grenoble Medical School.—Dr. Karpinki, formerly Extraordinary Professor of Surgical Appliances in the Military Medical Academy, St. Petersburg.—Dr. A. Caselli, Professor of Clinical Surgery in the Genoa Medical School.—Dr. Lienhart, Professor of Medical Botany in Lille.

UNIVERSITY OF CAMBRIDGE.—Lord Kitchener of Khartoum received a warm ovation on his visit for the purpose of receiving the freedom of the borough and the honorary doctorate of the university on Nov. 24th. At the same congregation Mr. H. Smith, M.A., Trinity, Mr. E. Harrison, M.A., Clare, and Mr. J. W. W. Stephens, B.A., Caius, were admitted to the M.D. degree. Mr. S. V. Roe, B.A., Pembroke, was admitted to the degrees of M.B. and B.C.

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITORS' ASSOCIATION.—The third annual dinner of this association was held at the Café Royal, Regent-street, on Saturday last, the President, Mr. F. Weiss, in the chair. The capital attendance and the encouraging tone of the speeches augur well for the future prosperity of this young association of those engaged in supplying the requirements of the medical profession. The last exhibition of the association was reported at length in THE LANCET of June 11th last.

PRESENTATION TO A MEDICAL MAN.—During a recent voyage of the steamer *Nineveh* from England to Australia a steerage passenger injured himself internally; an operation being immediately necessary Mr. E. M. Owens, L.R.C.P. Edin., M.R.C.S. Eng., surgeon to the steamer, operated in a gale with such success that the man walked off the ship three weeks later quite well. Chloroform was administered by the purser. At Messrs. Dalgety and Co.'s office, on Oct. 19th last, the captain of the steamer, on behalf of the owners, presented Mr. Owens with a travelling case and fittings as a memento of the voyage and of the single-handed operation in trying circumstances.

THE INSANITARY CONDITION OF MORRISTON.—On Nov. 22nd a deputation from Morriston appeared before the Water and Sewer Committee of the Swansea Town Council to complain of the insanitary condition of their neighbourhood. An extract from a sermon by the Vicar of Morriston bearing upon this matter was given in THE LANCET of Nov. 26th. The medical officer of health (Mr. E. Davies) reported that the whole district was in a lamentable condition and he recommended various improvements. A letter was read from the Local Government Board calling attention to the fact that there had been 96 fatal cases of diphtheria in the borough of Swansea and requesting a report from the medical officer of health upon the subject. It was decided to hold a special meeting to consider the report of the medical officer of health.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THURSDAY, NOV. 24TH.

THE proceedings of the first two days of the session of the Council were reported in last week's issue of THE LANCET. On the third day of the session there was again a full attendance of the members, Sir WILLIAM TURNER occupying the chair.

The Programme of Business.

Mr. HORSLEY said he desired to call attention to the fact that a friend of his, a registered medical practitioner, who attended the meeting of the Council as a member of the public in the public gallery, had asked to be supplied with a copy of the programme of business and had been refused. This was a novelty in practice, for hitherto persons in that capacity who attended the meetings of the Council had always been supplied with the programme. He had been so supplied himself before he was a member of the Council. He did not think the refusal was necessary, because the programme was more or less in the nature of a public document.

The PRESIDENT said that the programme of business was a confidential document and was marked with the word "confidential."

Mr. HORSLEY submitted that it ought not to be marked "confidential" and ought not to be so regarded.

The PRESIDENT assured Mr. Horsley that the matter had been considered repeatedly.

Mr. HORSLEY asked whether it had been discussed in the Council.

The PRESIDENT said he was not prepared to say that it had been actually discussed in the Council.

Mr. HORSLEY intimated that he would not pursue the matter further at present.

The Case of Frederic Mercer.

The Council then proceeded with the consideration of the case of Frederic Mercer, registered as of 141, Antill-road, E., Lic., Lic. Midwif. 1886, K. Q. Coll. Phys. Irel., who had been summoned to attend the Council to answer the following charge as formulated by the Council's solicitor:—

That, being a registered medical practitioner, he had in his employment an unqualified person named Bryden, whom he permitted and enabled to carry on medical practice and attend on and administer relief to patients as though he were duly qualified and whom he (Mercer) covered in the carrying on by him of a medical practice.

The name of the complainant is Mr. Alfred Henry Parker, of 142, Grove-road, Bethnal-green, registered as Lic. R. Coll. Phys. Edin. 1870, Lic. Soc. Apoth. Lond. 1870.

Mr. MERCER attended together with Mr. Bryden, his assistant, and Mr. Parker appeared to support his complaint.

Mr. MUIR MACKENZIE explained the circumstances of the case. Among other things he read the statutory declaration of Mr. Parker in which that gentleman said that on August 31st he received a message at his surgery to attend a midwifery case and when he went to the house he found Mr. Bryden in attendance on the patient. The child was born and Mr. Bryden was about to separate the cord. He said to the two women in attendance, "Oh, this is not my case," whereupon Mr. Bryden said, "No, this is Mr. Mercer's case." Mr. Parker afterwards met the husband who asked him, "Is it all right?" to which Mr. Parker replied, "Mr. Bryden was there." The husband said that he had called for Mr. Mercer and was told that he was engaged. Mr. Bryden offered to come to see his wife, but he (the husband) told him not to come as he knew it would be illegal. In a letter to the Registrar Mr. Mercer said that Mr. Bryden had attended the case under his personal supervision, he (Mr. Mercer) having visited the case three times on the day of the accouchement.

Mr. PARKER said he had no further legal proof to offer, but he would be glad to answer any questions addressed to him. In reply to members Mr. Parker said that Mr. Mercer and Mr. Bryden lived in the same house, the wife of the latter looking after the house. He had seen consultation papers issued by Mr. Mercer, on which the prices for midwifery and other matters were stated, and he asserted that the prices were cutting prices.

Dr. GLOVER: Do you understand the General Medical

Digitized by Google

Council in its late resolution to have forbidden a registered practitioner to allow his unqualified assistant to attend to midwifery?

Mr. PARKER: Really, I don't know. I asked the question and I was told that I ought to understand the law and go away and obey it. In one of my letters I say that I was under the impression that the employment of an unqualified assistant in the conduct of midwifery or any capacity other than surgery attendance is illegal but I asked for information.

Dr. GLOVER: And your object in coming here is to get an answer to that question?

Mr. PARKER: Precisely.

Dr. GLOVER: Whether the employment of an unqualified assistant in midwifery cases is a contravention of the rule of the Council?

Mr. PARKER: Precisely. I have no animosity against Mr. Mercer; I only want to get at the truth.

Mr. MERCER then addressed the Council. He said that on the day in question he visited the patient three times. Between the second and the third visit the people sent round to his house for him and when he called he found that Mr. Bryden had got there before him by some three or five minutes. He never allowed Mr. Bryden to make a visit on his behalf in any case of illness and he could only regard this complaint as the result of jealousy. Mr. Bryden's duty was simply to mix up medicine for him and if he did anything else it was under his direct personal supervision. Mr. Bryden lived in the house with him and Mrs. Bryden acted as his housekeeper, receiving a regular salary for what she did. He had since seen the husband of the patient and he made no complaint whatever about Mr. Bryden. As to the papers Mr. Mercer had spoken about they were prescription papers given only to patients and of course retained by them in order that the medicine might be renewed if required. In reply to questions Mr. Mercer said that when Mr. Bryden went to the house he knew that he (Mr. Mercer) would be there in a very few minutes. He believed that although Mr. Bryden had not gone through any regular course of study he had during his lifetime attended between 4000 and 5000 cases of midwifery. He had often lost cases through Mr. Bryden not being able to attend them, and he might say that to meet his increasing business he had recently engaged a qualified assistant. Eight years ago he (Mr. Mercer) was assisted by the late Dr. Rich, and it was at that time that he made the acquaintance of Mr. Bryden, who was an unqualified assistant to Dr. Rich. When he first saw the case in question he told the people that it would be a natural labour and that he would just look in occasionally. He was the most successful man in the district and they did all sorts of things to him; he believed they would kill him if they could.

Mr. BRYDEN, examined by Mr. Mercer, said that he had never attended midwifery cases without him (Mr. Mercer) nor had he ever attended any case of illness except under his personal supervision. The husband knew perfectly well that he was unqualified, but he made no complaint about him going to see his wife. He certainly had no recollection of the husband objecting to him going. It was a first case and the husband was very nervous, and he told him that Mr. Mercer would not be long in appearing on the scene.

In reply to members of the Council Mr. BRYDEN said that 25 or 26 years ago he was a student at the South Hants Infirmary, Southampton. He had not passed any preliminary examination nor had he attended any lectures, but he went round the beds with the medical officer on duty, who used to put questions to the students, and he had read up certain works. He had been an unqualified assistant ever since leaving the hospital. He had never gone to a midwifery case before when Mr. Mercer was out and he should not have gone in this case unless he had known that Mr. Mercer was on the way. His duties with Mr. Mercer were simply to dispense and take messages. Prior to this new regulation of the General Medical Council he regularly attended midwifery cases.

The Council, after deliberating *in camerâ*, decided that the charge made against Mr. Mercer had not been proved to its satisfaction.

The Case of John Lloyd Whitmarsh.

In the case of John Lloyd Whitmarsh, registered as of 3, Alfred-place West, South Kensington, Lic. Soc. Apoth. Lond. 1871, Lic. R. Coll. Phys. Edin. 1872, who on Oct. 24th at the Central Criminal Court was convicted of the murder of Alice Bayly and sentenced to death, a sentence since reduced to a period of penal servitude, the Council directed the Registrar to remove the name from the Medical Register.

The Case of Frederick Alfred Fisher.

The Council then proceeded to the consideration of the case of Frederick Alfred Fisher, of 29, Colebrooke-row, Islington, registered as Mem. R. Coll. Surg. Eng. 1869, Lic. R. Coll. Phys. Edin. 1870, Lic. Soc. Apoth. Lond. 1871, who had been summoned to answer the following charge as formulated by the Council's solicitor:—

That, being a registered medical practitioner, he seeks to attract practice by public advertisements, containing invitations to persons to consult him professionally at an address named in the advertisements, which advertisements published by him or to the publication of which he was a party were themselves of a character grossly discreditable to a professional medical practitioner. The advertisements complained of were those of an institution called Nervous Debility Dispensary, City-road, E.C., and had been published in the advertisement columns of the *People* newspaper and elsewhere,

The complainants are the Incorporated Medical Practitioners' Association.

Mr. Fisher did not appear. The complainants were represented by Dr. Hugh Woods, President of the Incorporated Medical Practitioners' Association, with whom was Mr. R. R. More Madden.

Mr. MUIR MACKENZIE read the documents in the case, including a letter from Mr. Fisher stating that the writer was at a loss to understand why he should receive a summons from the General Medical Council, seeing that it was now twelve years ago since he had sent a letter to the Council requesting that his name should be taken off the Medical Register.

The PRESIDENT said that there was no record in the Council's office of the receipt or acknowledgment of any such letter. He directed the case to proceed.

Dr. WOODS thereupon said that "advertising" was becoming quite prevalent in the medical profession. Innumerable cases were being seen, to the disgrace of the profession. For example, they knew of a "doctor" who was going about carrying a black bag and pushing handbills advertising himself under the doors of all the houses in his locality. But the worst of it was that there was an increase in the practice of advertising in the newspapers, the announcements in these being almost always of an indecent character relating to private ailments and ailments of a delicate character. These tended to bring the medical profession into disrepute and the society to which he belonged was anxious to get the General Medical Council to follow the example of the Incorporated Law Society and the Stock Exchange, and declare that advertising by registered medical practitioners was infamous conduct in a professional respect. Advertising was no doubt profitable in a pecuniary sense, but as the respectable members of the profession considered it degrading to advertise and as the Council were opposed to it, those who got the profit were the less respectable members of the profession, and the Council should see that they should not have the opportunity to carry on their business unless on terms of equality.

Dr. MCVAIL asked if Dr. Woods was prepared to prove the identity of the Mr. Fisher of Colebrooke-row with the Mr. Fisher of the City-road.

Dr. WOODS thought the letter from Mr. Fisher contained the admission that the Mr. Fisher of Colebrooke-row was the Mr. Fisher of the City-road. He had made careful inquiries and found that the two addresses were those of the same man and he could bring a witness to prove it if it were necessary.

Mr. MUIR MACKENZIE said that in the absence of any dispute to the contrary the Council should consider that identity was proved.

The PRESIDENT thereupon invited Dr. Woods to proceed.

Dr. WOODS said it was high time that a definite understanding was come to as to whether advertising was to be allowed. If Mr. Fisher was not entitled to advertise, advertising as in his case should be declared infamous conduct.

The PRESIDENT said he did not think Dr. Woods need argue that matter, which was already settled so far as the General Medical Council and the Courts of Law were concerned.

Dr. WOODS said that there then could be no hardship in dealing with Mr. Fisher who, as shown by his letter, did not value the privilege of registration. In the circumstances he thought the Council need not hesitate in taking effective steps to stop the pernicious practice now complained of.

Some conversation followed and in the course of it

Digitized by Google

Sir RICHARD THORNE again raised the question of identity He said there were at least two men of the name of Fisher on the Register and both of them had the same medical degrees.

Dr. LOMBE ATTHILL was not sure that identity had been established.

Dr. WOODS said that Dr. Cook, who had lived for many years at Islington, had informed him that the men of the two addresses were one and the same. Dr. Cook lived in the country and he (Dr. Woods) had thought it unnecessary to bring him to London to prove his statement to the Council direct. If, however, there was doubt of a serious nature he should ask that the case should be adjourned so that he might call evidence.

Dr. MCVAIL thought the Council could not go on without evidence of identity and he moved the adjournment of consideration of the case.

Dr. LOMBE ATTHILL seconded the motion, which after some further conversation was put to the vote and was declared to be lost on its being found that it was supported by only six of the members present.

The case thereupon proceeded on its merits.

In answer to Dr. MACALISTER Dr. WOODS explained that no communication whatever had been made by the complainants to the Mr. Fisher summoned previously to the proceedings being taken before the Council.

After the Council had deliberated in private for some time

The PRESIDENT announced that they judged Mr. Fisher guilty of infamous conduct in a professional respect and now directed the Registrar to erase his name from the Medical Register.

Mr. BROWN, as a member of the Incorporated Medical Practitioners' Association, took no part in the consideration of the case.

The Case of the late Mr. H. Kingsley Hunter.

Mr. BROWN said he rose as a matter of urgency to make a motion on this case, seeing that the Council's legal advisers were present. He and Mr. Horsley on the preceding night had had an opportunity of inspecting the papers in the case. The Hunter case——

The PRESIDENT asked whether the Council should not discuss this matter *in camerâ*.

Mr. BROWN thought that what he was going to say should be spoken in public as it was of great importance to the profession.

Sir CHRISTOPHER NIXON said that as the case was *sub judice* surely it should not be brought forward unless when the Council were *in camerâ*.

Dr. MACALISTER wanted to know whether Mr. Brown was to bring forward a motion.

Mr. BROWN replied that he was. The motion was on the programme of business.

Dr. MACALISTER said that the motion was on the programme for the following day.

The PRESIDENT said that in that case Mr. Brown would in the first instance have to get the permission of the Council to go on.

Mr. BROWN said he was not going into the merits of the case. He simply just now wished to know if Mr. Muir Mackenzie could inform the Council whether it was the fact that the Hunter case was to be taken within the next few days.

Mr. MUIR MACKENZIE replied that he had endeavoured to get the case brought forward before the present session of Council, but he had been unsuccessful, and it was now uncertain on what day the court would hear it. The appellant (Mr. Hunter) was dead, and some of the officers of the Court of Queen's Bench were of opinion—well, he hesitated to make the statement.

The PRESIDENT: We should hear it in private.

Mr. BROWN said he had now no objection that they should go *in camerâ*.

Strangers were thereupon ordered to withdraw and the Council discussed the matter in private during the remainder of the sitting.

FRIDAY, NOV. 25TH.

The Council resumed work to-day, Sir WILLIAM TURNER being in the chair.

The Case of James Havard Jones.

The entire sitting of the Council was occupied with the consideration of the case of James Havard Jones, registered as of Ogo, Llandyssil, Carmarthenshire, M.B., Mast. Surg. 1894, Univ. Edin., who had been summoned to answer the following charge as formulated by the Council's solicitor:—

That, being a registered medical practitioner, he covers an unqualified person named George Jenkins in the carrying on by such unqualified person of a medical practice, and permits and by his presence and assistance enables the said George Jenkins to carry on a medical practice and attend to administer relief to patients as though he were duly qualified.

The name of the complainant is Dr. John Jones, of Clydach, Swansea, registered as M.B., Bac. Surg. 1892, M.D. 1893, Univ. Lond., Mem. R. Coll. Surg. Eng. 1892, Lic. R. Coll. Phys. Lond. 1892.

Dr. Havard Jones attended with Mr. Lawson Walton, Q.C. instructed by Mr. David Randell, and Dr. John Jones attended without legal assistance.

Dr. JOHN JONES, presenting his case to the Council, said that Mr. Jenkins was a prominent man in the village of Clydach. He had resided there for nearly thirty years and as an unqualified assistant had been in the employment of successive medical men. He (Dr. John Jones) had employed him, but on Jan. 1st, 1898, in obedience to the new rule of the General Medical Council, he had dispensed with his services. On that day also he had forwarded to each of the works in the district a copy of the new rule along with a letter saying that owing to the rule he was not in a position to employ Mr. Jenkins any longer as an unqualified assistant. On receipt of his communication the employés at the various works met together and selected two of their number from each works to act as delegates. These delegates met together for the purpose of discussing the situation and deciding what steps should be taken, as there were a number of the men who had grown accustomed to the services of Mr. Jenkins and were not willing to see them dispensed with or Mr. Jenkins put on one side. Mr. Jenkins attended the meeting, but he (Dr. John Jones) declined to attend, though he agreed to meet representatives at his own house and discuss the situation with them there. He explained to these representatives that he had dispensed with the services of Mr. Jenkins because of the new rule of the General Medical Council, and in the end the meeting decided to offer the appointment of medical officer to Dr. Havard Jones on condition that he employed Mr. Jenkins. He (Dr. John Jones) resigned his appointment, but afterwards offered himself for reappointment. Dr. Havard Jones, a total stranger in the district, accepted the appointment, came to Clydach, and at once established himself in the house and surgery of Mr. Jenkins. Since then he had been constantly driving and walking about with Mr. Jenkins. Dr. John Jones proceeded to read to the Council a number of declarations. One made by himself referred to a visit he had seen Mr. Jenkins pay to a farmhouse where a woman had been confined two days before; another stated that Mr. Jenkins was almost every day to be seen in the company of Dr. Havard Jones; and a third dealt with a visit paid by Mr. Jenkins to the house of a man who was suffering from sore-throat.

Examined by Mr. LAWSON WALTON, Q.C., Dr. JOHN JONES said that Mr. Jenkins was in his employment from May, 1895, until Jan. 1st, 1898, and he had no other ground for dispensing with his services than the new resolution of the General Medical Council nor did he assign any other cause. He admitted that many of the miners considered Mr. Jenkins had been somewhat hardly used, but there was no capacity in which he (Dr. John Jones) could give him further employment.

Mr. RICHARD LLEWELYN DAVIES, chemist, Clydach, gave evidence as to seeing Mr. Jenkins walking and driving about with Dr. Havard Jones.

Mr. LAWSON WALTON, Q.C., then addressed the Council on behalf of Dr. Havard Jones. He submitted that Dr. John Jones had entirely failed to prove his charge of covering. He had brought no evidence to show that patients had been treated by Mr. Jenkins since the arrival of Dr. Havard Jones upon the scene. At the same time his client, jealous of his professional honour and reputation, desired to put his version of the case before the Council. Dr. Havard Jones was brought to the village knowing very little of the quarrel which had taken place. Practically all he knew was that there was a vacancy which either he or some other medical man would have to fill. Mr. Jenkins had been continuously employed in the village for thirty years by successive medical men. He was not concerned to defend his employment but it was the fact that Mr. Jenkins was a man of high character and he was greatly

Digitized by Google

beloved by the people among whom he had worked during all these years. Suddenly and after Dr. John Jones had availed himself of Mr. Jenkins's services for over two years he discharged him. From the point of view of this Council it was a proper discharge, but from the point of view of these workmen it could easily be understood that Mr. Jenkins became an object of very great sympathy, and it was thought, rightly or wrongly, that Dr. John Jones had acted harshly in the matter. Mr. Jenkins had a house, the most important house in the village, and a surgery stocked with drugs; and he had also a horse and trap, and to be dismissed at once from his employment without any sort of compensation was a most serious matter for him. It was thought that Dr. John Jones might have attended the meeting of delegates and discussed the matter, because the men did not see why he should be unable to find some sort of legitimate employment for Mr. Jenkins. He did not, however, attend, and, further, he sent in his resignation. Various other medical men were approached and among them Dr. Havard Jones, who went to see the place. On his return home Dr. Havard Jones sent a telegram saying: "Cannot possibly accept appointment while Jenkins has anything to do with the practice," and he received a letter from Mr. Jenkins saying that he was ready to obey and respect the wish of the General Medical Council not to do anything as an assistant to any medical practitioner. Mr. Jenkins said further that he was in bad health and was going away to Scotland, but he would leave it to his daughter to arrange about the use of the house and surgery and the horse and trap. Dr. Havard Jones went to Mr. Jenkins's house and resided there because there was no other eligible house in the village, and for the use of it and the surgery and the horse and trap and his board he agreed with Mr. Jenkins's daughter to pay £15 per month. In accepting the appointment Dr. Havard Jones fettered himself in no way with regard to Mr. Jenkins, nor had he employed that gentleman in any capacity whatsoever. As to Dr. Havard Jones being seen walking and driving with Mr. Jenkins, there was no reason why the two men should not enjoy each other's company if they wished it. Mr. Jenkins certainly visited the farmhouse where there had been a confinement, but he did not visit as a medical man nor did he even see the patient. As to the sore-throat case, in that also he never saw the patient.

Dr. HAVARD JONES gave evidence to bear out the statement of his counsel. He insisted that he should never have accepted the appointment unless he had received the assurance that Mr. Jenkins would refrain from practice of any kind and he denied that he had entered into any agreement with the workmen to employ Mr. Jenkins. After his appointment he at once advertised for a qualified assistant, and though qualified assistants for such a village were ill to find he might say that he now had one.

Cross-examined by Dr. JOHN JONES witness said that he had never promised to find Mr. Jenkins a respectable livelihood.

In reply to members of the Council Dr. HAVARD JONES said that he had to pay the expenses of the stable-boy and the horse's food in addition to the £15 a month. When the workmen first approached him they asked whether he could do anything for Mr. Jenkins and he told them plainly that he could not employ him in any way. The value of the appointments, exclusive of private practice, was about £500 a year.

Mr. GEORGE JENKINS, examined by Mr. LAWSON WALTON, Q.C., denied that he had attended a single case since the appointment of Dr. Havard Jones or that he had made any agreement with that gentleman to assist him in any way with the practice.

Cross-examined by Dr. JOHN JONES witness said he informed the workmen that in consequence of the action of the General Medical Council he could no longer act as he had been doing.

In reply to members of the Council he said he was not sure about the valuation of his house, but he thought it was £12 10*s.*, and the horse and trap would be worth about £30. He had never attended any medical school, but he was apprenticed to a chemist in 1856. Under Dr. John Jones his income was about £200 a year, and he supposed the surgery and the horse and trap would cost him about £50 a year. The sum of £15 a month paid by Dr. Havard Jones went to his daughter, who looked after the house; he himself had never touched a penny of it. He denied that there was any truth in the suggestion that the workmen made it a condition with Dr. Havard Jones that he should employ him.

Mr. THOMAS EVANS, manager of one of the works, gave evidence to the effect that employment of Mr. Jenkins was not one of the conditions of the engagement of Dr. Havard Jones.

At this stage in the proceedings the Council adjourned.

SATURDAY, NOV. 26TH.

The Council met again to-day, Sir WILLIAM TURNER presiding.

The Case of James Havard Jones: Decision of the Council.

After approving the minutes of the previous sitting the Council proceeded *in camerâ* to consider its decision in the case of Dr. James Havard Jones. This matter occupied nearly an hour and a half, at the end of which time parties and strangers were readmitted and the President announced that the Council had come to the judgment that the charge against Dr. Havard Jones had not been proved to the satisfaction of the Council.

The Programme of Business.

Mr. HORSLEY asked leave as a matter of urgency to call attention to a breach of Standing Order, Chapter IV., Clause 7.

Sir JOHN BATTY TUKE protested against leave being given having regard to the important business which the Council had still to discuss.

Sir CHRISTOPHER NIXON said that while he regretted anything in the nature of waste of time they must be careful to see that their Standing Orders were not violated.

On a show of hands being taken 10 were held up for leave and 11 against it, but when the names and numbers were called for it was found that 12 members voted for leave and 11 voted against it.

Mr. HORSLEY accordingly proceeded with his notice. The Standing Order in question, he said, set forth that at the beginning of each session the Council should appoint a Business Committee whose duty it would be to prepare a daily programme of business containing subjects to be brought forward and notices of motion given by members and this programme would be printed and distributed from day to day as required. His only point was that he sent in to the Registrar a notice of motion for insertion in the programme, and while it was perfectly true that the subject to which the motion referred was brought up on an occasion when the Council was *in camerâ* he did not move that the Council go *in camerâ*, but, on the contrary, he desired that the subject should be discussed in public. He submitted that, in spite of what had occurred *in camerâ*, the motion should not be excluded from the programme of business but should have a place there.

Dr. MACALISTER, chairman of the Business Committee, said that the minutes of what was done *in camerâ* would be read when next they were *in camerâ*, and they would show that the motion had been adjourned without any action taken. In these circumstances he submitted it would have been most improper to put down the motion on the programme of business as if it had not been discussed.

After some slight discussion Mr. HORSLEY agreed not to press the matter.

Amendments in the Standing Orders.

The Council then went into committee to consider in detail a report prepared by the Executive Committee with regard to certain proposed alterations in the Standing Orders.

Sir DYCE DUCKWORTH said that the first recommendation in the report had reference to the work of committees and it proposed that the Standing Order on this subject should read:—

> Each committee shall once a year at least make a report upon the subject referred to it by the Council and each committee shall be convened at the discretion of its chairman.

He moved the adoption of this recommendation.

Mr. CARTER seconded the motion.

Mr. HORSLEY thought the summoning of a committee should not be left entirely in the hands of the chairman, but that it should be open to any two members to requisition a meeting.

Dr. MACALISTER expressed his preference for what the Executive Committee proposed.

Dr. BRUCE moved as an amendment to add the words "or upon the requisition of a majority of the committee," and Dr. LEECH seconded the amendment.

Digitized by Google

Mr. HORSLEY said he was prepared to accept this amendment.

The amendment on being put to the committee was adopted by a large majority and the words accordingly were added to the Standing Order.

Sir DYCE DUCKWORTH said that the second recommendation of the Executive Committee had reference to the Penal Cases Committee. It had been proposed that this committee like the others should be appointed annually, but the Executive Committee had not seen their way to propose this, being of opinion that it was undesirable to make frequent changes in the composition of the Penal Cases Committee. What they recommended was that vacancies in this committee should be filled as they occurred and then on the nomination of the Branch Council to which the member retiring or ceasing to act had belonged, and he moved accordingly.

Mr. CARTER seconded the adoption of this recommendation.

Mr. HORSLEY suggested that this matter should be postponed by the committee until a decision had been come to on the following notice of motion which stood on the programme of business in the name of Mr. Brown, viz.:—

That Standing Order IX. as far as relates to the Penal Cases Committee be and is hereby repealed and that the duties hitherto discharged by the Penal Cases Committee be referred to the respective Branch Councils.

Dr. MACALISTER pointed out that postponement would not be necessary if Mr. Brown were allowed to move this now as an amendment to the recommendation of the Executive Committee.

The committee decided to adopt this course of procedure.

Mr. BROWN said that while he had not expected his motion to be reached to-day, and consequently was not prepared with all his material to support it, he would undertake to move it. He could not say that he was at all satisfied with the way penal cases were presented to the Council by the Penal Cases Committee. He felt sure that many cases were presented to the Council which ought never to have been presented. He had no need to go far back for an example, for the last case disposed of was a most typical example. They had spent nearly two days in examining a case which one of his colleagues said never ought to have been brought before the Council at all. It surely was a very serious thing that the Penal Cases Committee should have reported to the Council a case which, in the opinion of one of the members of the Council, ought never to have come before the Council in the shape in which it did. Let the Council bear in mind that in the matter of attendance fees this single case had cost about 250 guineas and he put it to the Council whether it was reasonable or in accordance with common sense that thirty gentlemen should sit there in judgment upon a case, first as jurymen and then as judges, when a much smaller and less expensive body could do it.

The PRESIDENT: Stop one moment. Are you really going to argue that all these penal cases should be disposed of by the respective Branch Councils?

Mr. BROWN said he was coming to that. The proposition he desired to put before them was that all penal cases should be referred to the Branch Councils in the respective divisions of the kingdom where they occurred, that the Branch Councils should have power to call evidence and examine witnesses, and having consulted with a legal assessor should recommend to the Council the course which should be taken. All the evidence upon which the recommendation was based would be printed and circulated amongst the members of the Council, and the result would be that instead of going into the whole case, and each member of the Council cross-examining the witnesses and so much time being taken up, he Council would be able to get through the whole of the penal work in one afternoon's sitting, even if there were a dozen cases. The economy of this arrangement would be appreciated when they considered the difference between a sitting of thirty members at 5 guineas each and one of fourteen members at 2 guineas each.

The PRESIDENT, interrupting Mr. Brown, said he thought he was bound to show that the Council would be fulfilling the statute by acting in the manner he proposed.

Mr. BROWN said that the proceedings of the Council showed that they could remit important duties to their committees, and with regard to the Branch Councils Section 6 of the Act of 1858 said that to these "shall be delegated such of the powers and duties vested in the Council as the Council may see fit other than the power to make representations to Her Majesty in Council as hereinafter mentioned." If members consulted the minutes of twenty-five or thirty years ago they would see that at that time most important work was done by the Branch Councils, whereas nowadays they did practically nothing, and he submitted that if what he now proposed were adopted the arrangements would prove beneficial to the Branch Councils and to the General Council and to all the other interests concerned.

Mr. HORSLEY, seconding the amendment, said that he had considered the whole situation and had come to the conclusion that it would be better if a number of these cases were disposed of by the Branch Councils. Any serious case would, of course, be passed on to the General Council.

The PRESIDENT: A Branch Council cannot come to a decision to put a man off the Register.

Mr. HORSLEY: Nor do I propose that it should. But I say "disposed of" certainly because cases are disposed of now by the Penal Cases Committee.

The PRESIDENT: Disposed of in the same sense of not being proceeded with.

Mr. HORSLEY said that if a complaint were made by a practitioner to this Council the complaint might only be discussed by a small committee and might not be proceeded with, and altogether he thought the work would be much better done by the Branch Councils than by this committee and for this reason he seconded the amendment.

The PRESIDENT said he desired to point out that Mr. Brown in his speech went very much beyond the terms of his amendment, which were that the existing Standing Order be repealed and that the duties hitherto discharged by the Penal Cases Committee be referred to the respective Branch Councils. An important point in Mr. Brown's speech was that the Branch Councils should be empowered to take evidence. Now the Penal Cases Committee took no evidence in the sense of summoning people, in that respect being unlike the Dental Committee. Supposing they had the power to do what Mr. Brown proposed he did not see how it would effect economy either of time or money, because the evidence must be heard by the General Council before it pronounced judgment.

Mr. BROWN submitted that under the section of the Act of 1858 to which he had referred the General Council had power to delegate its powers to the Branch Councils. He should be glad to hear the views of Mr. Muir Mackenzie on the subject.

Mr. MUIR MACKENZIE said that this question was very fully and exhaustively considered during the time the late Mr. Marshall was President of the Council. He had a large number of consultations with Mr. Marshall and he received his instructions to draw for submission to Parliament a Bill which would have carried out in effect the proposal which Mr. Brown now put forward. But an opinion given a very considerable number of years ago by the late Lord Chief Justice Coleridge when at the bar and Lord Justice Bowen when at the bar was to the effect that for the purpose of an inquiry under Section 29 of the Act of 1858 the whole of the evidence must be heard by the Council and no erasure of a name under that section would be valid unless all the evidence for and against was heard and judicially determined upon by the whole of the Council. By the whole of the Council of course he meant subject to any member being absent. There was, he believed, no power to delegate any part of the inquiry upon which the practitioner was standing his trial either to the Branch Councils or any committee. Of course, a preliminary sifting to see whether there was any case at all with which the Council should be troubled was quite a different thing, though that in itself was a matter to be dealt with with some care, because in two of the cases taken to courts of law in which the procedure of the Council was questioned one of the points in each case was that evidence of facts had been before members of the committee of the Council before the inquiry, and it was contended that this was contrary to natural justice. It was contended that all the evidence should be heard before one body, but of course when it was shown to the court that all that had happened was that there had been a preliminary sifting of the complaint to see whether it ought to go before the whole Council it was seen that that was quite a different thing. All he was speaking of was the question whether the Branch Councils could hear evidence and make a report upon which the General Council could act. That he was distinctly of opinion would render the inquiry invalid and the practitioner whose name was erased upon such an inquiry would be entitled to apply for a mandamus to have his name restored. He hoped that upon a question of this

Digitized by Google

kind the Council would act with great caution, bearing in mind that when a practitioner's name was erased generally every kind of step in the procedure was vigilantly scrutinised to see if there had been any single false step by means of which the matter could be reviewed in a court of law, and it was a matter with which the Council might rest satisfied that all the attacks made upon the procedure had failed.

Mr. HORSLEY said he quite agreed that the whole evidence must be heard by the Council and all he contended was that this preliminary sifting would be more effectively and more economically done by the Branch Councils than by the Penal Cases Committee.

Dr. GLOVER believed that if Mr. Brown's proposal was adopted and the system of investigation by Branch Councils instituted it would tend to economy. Moreover, he thought it would be better if the facts submitted to the Penal Cases Committee were dealt with by men with local knowledge. For such reasons he was prepared to support the amendment.

Dr. BRUCE said he had all along been of opinion that the Branch Councils should have charge of penal cases arising in their respective districts. It was true that very few of these cases came from Ireland or from Scotland, but from whichever part of the United Kingdom they came it would be a great advantage to have them sifted by the Branch Councils.

Mr. BRUDENELL CARTER thought it was possible that some members of Council did not fully realise what it was that the Penal Cases Committee were called upon to do. That committee had no power to sift facts. All that was placed before them were statements of alleged misconduct on the part of practitioners, and all the committee could do was to see that these statements were substantiated by statutory declarations, and then if they disclosed an offence under the Medical Act to order the cases to go before the Council. As to whether an offence against the Medical Act was disclosed the committee were guided by the advice of Mr. Muir Mackenzie. If no offence was disclosed the committee, of course, would not be justified in carrying the case further. That outline of the committee's work showed that it was not the case that it had the sifting of facts. It seemed to him that it would be entirely inadvisable to call in the Branch Councils to do what two or three men in the exercise of common sense did very well. The Penal Cases Committee were valuable because of their knowledge of things which had come up in past years. They saved the Council a great deal of trouble and put it to no expense. He could not think that Mr. Brown had thought out the case he wished to make, and even if the suggested system were introduced he did not think it would lead in any instance to a result different from that which would be obtained under the present system.

Mr. BROWN, in replying on the discussion, explained that he had brought forward the proposal because he was not satisfied, as Mr. Carter was, that the Penal Cases Committee had done the work quite well. His impression was that the committee had failed to do the work quite well. According to his view they had blundered and thus had placed the Council in a position such as they must regret. From investigations which he had made it seemed to him that the committee did not know the facts of a case in which they had recommended prosecution.

Several members cried "No, no," and the PRESIDENT expressed the opinion that Mr. Brown was going beyond the limits of a reply.

Mr. BROWN reminded the Council that Mr. Carter had said "the committee did the work quite well." He (Mr. Brown) replied that they had blundered, that they had not sifted the facts. If he were not to be allowed to bring that point before the Council that day he certainly should take an opportunity of doing so on another day. He was not going to delegate his responsibility to a committee who had advised the Council in a way that they had not the courage to stand up and defend.

Dr. GLOVER rose to a point of order. He said that he was a member of the Penal Cases Committee and he was quite prepared to deal with the matter Mr. Brown was hinting at when it was raised in a proper form. He put it to Mr. Brown whether he thought it fair by innuendos and without giving names to say what he had said.

Mr. BROWN: Mr. Carter said the committee did the work quite well and I said they did not do so, and I gave the case alluded to as an instance that the committee had blundered.

Dr. GLOVER: I ask Mr. Brown if he thinks it fair by innuendo to make a charge against the Penal Cases Committee.

Mr. BROWN: You (Dr. Glover) know the case to which I refer. I do think it fair when a member of the Penal Cases Committee says that that committee has done its work quite well.

The amendment was then put to the vote. On a show of hands 5 voted for the amendment and 20 against it. The roll on Mr. Brown's demand was thereupon called, when 20 voted against it and 6 for it, 3 declining to vote. Mr. Brown's amendment accordingly was defeated.

The recommendation of the Executive Committee was then further discussed.

Mr. TOMES was of opinion that the recommendation was too drastic. There should, he said, be some means by which change in the membership should be secured other than that of filling vacancies when they occurred.

Mr. BROWN: Even the Executive Committee is elected every year.

Mr. HORSLEY: That is exactly the reason why I put my motion down on the paper. It does not follow that we do not reappoint them if they have done the work well. This suggestion of the Executive Committee assumes that there is going to be a wholesale change. That is not required or contemplated. All that is wanted is that the committee should be placed on the same footing as other committees of Council. There is no reason why the Penal Cases Committee should be a standing committee.

Mr. BRUDENELL CARTER moved the adjournment of the debate.

The Council resumed, and after an intimation by the PRESIDENT to the effect that many members had expressed the wish that the session should terminate on the Tuesday of the following week the Council adjourned.

MONDAY, NOV. 28TH.

The Council met again to-day, Sir WILLIAM TURNER being in the chair.

The Hunter Appeal Case.

Mr. HORSLEY asked that the first item on the programme be postponed in order that he might draw attention to the procedure of the Penal Cases Committee in relation to the Hunter appeal case now pending and move a resolution thereon.

On the question that leave be given to Mr. Horsley 6 members voted for leave and 21 against it. Leave was consequently refused.

Amendment of the Standing Orders.

The Council then went into committee and resumed the consideration of the report of the Executive Committee in regard to certain proposed amendments in the Standing Orders. When the consideration of the report was adjourned on Saturday Sir Dyce Duckworth had moved the adoption of the second recommendation of the committee, which was to this effect:—

That vacancies in the Penal Cases Committee should be filled as they occur and then on the nomination of the Branch Council to which the member retiring or ceasing to act has belonged.

Mr. BRUDENELL CARTER said that the Executive Committee in making this recommendation felt that the Penal Cases Committee differed in the nature of its functions from the other committees of the Council and that its constitution might therefore be different. It was a committee primarily formed to assist the President in his function of deciding whether a given complaint should or should not be submitted to the Council for its consideration. In the first instance the President merely invited a few of the members to confer with him upon questions of this kind and he finally asked the Council to appoint a small committee of members resident in London who could be easily brought together at any convenient time for this particular purpose. It seemed to him that the principle, undoubtedly sound, of changing the *personnel* of committees from time to time was not so applicable in this case.

Dr. BRUCE said he saw no reason why the principle should not apply to the Penal Cases Committee, and he felt certain that in working it out there would be no disposition on the part of the Council to make very frequent changes.

Sir RICHARD THORNE objected to the idea of appointing men for life to any committee.

Mr. TOMES said that if they passed this recommendation they would only be able to get a change upon the committee by indicting one or more of the members.

Digitized by Google

Dr. GLOVER intimated that he did not see his way to support this recommendation.

Sir RICHARD THORNE said he would move as an amendment:

That the Penal Cases Committee be elected annually in May in the same manner as the Executive Committee.

Dr. ATTHILL seconded this amendment.

This amendment was at once adopted and became the resolution of the committee.

Sir DYCE DUCKWORTH moved the adoption of the third recommendation, which in effect was that the Penal Cases Committee should meet four times a year if necessary or oftener if, in the opinion of the President, the occasion arose.

This recommendation was agreed to after a short debate.

The fourth recommendation, which had reference to the preparation and approval of abstracts of complaints, was also agreed to.

Sir DYCE DUCKWORTH moved the adoption of the fifth recommendation, but after some debate it was agreed to refer the subject matter back to the committee for further consideration.

The sixth recommendation, dealing with the procedure with regard to the service of the notice upon the accused practitioner, was agreed to.

Sir DYCE DUCKWORTH said that the seventh recommendation referred to the proposal of Mr. Horsley that "when any answer, evidence, or statement is forwarded, or application made by the accused person between the date of the issue of the notice and the date named for the hearing of the charge, copies thereof shall be immediately sent by the Registrar to each member of the Penal Cases Committee." The Executive Committee recommended that it was unnecessary to adopt the proposal seeing that the Standing Order provided that all members of the Council should receive not less than three days before the meeting copies of the documents in the penal cases to be brought before the Council. He moved the adoption of this recommendation.

Mr. HORSLEY moved as an amendment the proposal which Sir Dyce Duckworth had read. He considered it of vital importance that the committee should be possessed of all the documents sent to the office before the case came on for trial.

Mr. BROWN seconded the amendment.

Dr. GLOVER supported the amendment, saying that he did not see why the Penal Cases Committee should be deprived of prompt delivery of any new documents.

Sir CHRISTOPHER NIXON said that the delivery of fresh documents might enable the committee to withdraw the charge and thus save the time of the Council.

Mr. CARTER doubted whether the committee possessed power to withdraw the charge.

Dr. MACALISTER said he objected to the idea of the committee behind the back of the Council withdrawing a charge.

The PRESIDENT said he doubted whether the Council would give the committee power to withdraw a charge after the summons had been issued.

On a vote being taken the amendment was rejected and the recommendation of the committee adopted. The Council also adopted the eighth recommendation, which referred to the same subject.

Sir DYCE DUCKWORTH asked the Council to adopt the ninth recommendation, the effect of which was to empower the President if he thought fit to instruct the Registrar to ask the accused person for any explanation he might have to offer.

The PRESIDENT explained that he had found in practice that it was very desirable he should be invested with this power. It might very well happen that the accused person had a perfectly valid explanation to offer.

The recommendation having been adopted the Council resumed and Dr. MACALISTER brought up a report of the proceedings in committee of the whole Council.

It was agreed that the alterations made in the Standing Orders be adopted by the Council provided that Mr. Muir Mackenzie, as legal adviser, raised no objection to them of a legal character.

The Direct Representatives.

Mr. BROWN said that for several days there had appeared against his name in the programme of business two notices of motion to the effect that the time had come for giving the Scotch and the Irish practitioners power to elect each an additional Direct Representative. It had been suggested to him that these motions would come better from Scotch and Irish members and therefore he desired to withdraw them.

The PRESIDENT asked Mr. Brown whether he also wished to withdraw his motion with regard to the English practitioners.

Mr. BROWN: Oh, no.

Preliminary Examinations: an Important Report.

The Council next, on the formal motion of Sir JOHN BATTY TUKE, seconded by Dr. MACALISTER, received a report by the Education Committee on the revision of the list of recognised preliminary examinations in general education.

The report contained the following passages:—

Under instructions from the Council the Education Committee have during the past year been engaged in the revision of the list of recognised preliminary examinations, with a view to removing from it on the 1st day of January, 1900, those examinations which are of a lower standard than that prescribed by the Council in its resolution of Nov. 29th, 1897. They have, in reply to their inquiries, received a large amount of information from bodies and persons concerned and have also had to consider a number of other communications referred to them by direction of the President. It will be convenient to deal with these in some detail before proceeding to state the final conclusions of the committee in regard to them and to the subject in general.

The more important of the communications are:—

1. A "statement respecting the standard of the College of Preceptors' Second-class Examinations as compared with that of the University Junior Local Examinations."
2. A letter on the "Conjoint Examinations in Ireland by the Royal College of Physicians and Royal College of Surgeons," with accompanying papers sent by the secretary.
3. Letters from Dr. Alexander Mackay sent with other papers on behalf of the Educational Institute of Scotland.
4. Communications from the Secretary of State for the Colonies in reference to the recognition of the examinations, &c., of the University of Malta.
5. Certain other communications from Indian and Colonial universities and educational bodies in reference to their examinations.

I.—The Council of the College of Preceptors has drawn up and circulated for the information of the General Medical Council an elaborate "statement respecting the standard of the College of Preceptors' Second-class Examinations as compared with that of the University Junior Local Examinations." The Education Committee have given the statement their best consideration and have had before them a large body of evidence on the questions which it raises.

The committee have already reported to the Council their conclusion that the examination in question is not of the standard desired by the Council, and that in their opinion it should be removed from the list as from Jan. 1st, 1900.

The considerations which have confirmed the committee in their conclusion are the following:—

1. During the years 1892-98 returns have been made to the Council, on behalf of the Examining Boards for the Navy, Army, and Indian Medical Services, respecting those candidates for appointments who showed deficiency in general education. In the case of ten of these candidates the particulars given were insufficient to enable the preliminary examination to be traced; in the case of 29 the examination passed by the candidate was one of those at present recognised by the Council. In no less than 14 instances the examination by which the candidate had gained admission to the Students' Register was that of the College of Preceptors, while the remaining 15 candidates had qualified by one or other of *nine* of the recognised examinations. There were, in addition, 16 candidates who had qualified for registration by means of the examinations of the Society of Apothecaries or the Royal College of Surgeons in Ireland, but the examinations have now for some years been discontinued.

It thus appears that of all the examinations now on the Council's list the College of Preceptors' is that which most frequently gives rise to animadversion on the part of the examining boards and that the college contributes to the returns of comparative failure almost as many instances as all the other educational bodies together. It is also worthy of note that the returns report no single instance of deficiency in general education on the part of a student registered by means of a university local examination.

2. The committee have had before them the results of a careful investigation of the regulations, the papers of questions, and the answers of candidates who obtained pass marks in the College of Preceptors' examination and the conditions under which such candidates failed or succeeded in obtaining qualifying certificates. All the points on which a conclusion regarding the actual standard and quality of the examination should be based were taken into account. The result was a conviction that on its merits the examination was not sufficient to ensure that all who passed it had reached the standard of general knowledge and intellectual training desired by the Council.

3. The committee on a previous occasion expressed their thanks to the authorities of the College of Preceptors for the facilities accorded them in making their inquiries. Similar acknowledgments are due to the English university bodies controlling the local examinations for granting the committee permission to inspect the answers of candidates who are certified as having satisfied the requirements of the Council. These bodies have, moreover, placed at the disposal of the committee for its information full details as to their standards, methods, and statistics, and these, which are communicated confidentially, together with the published reports, have enabled the committee to form an estimate of the relative efficiency of the examination with which the College of Preceptors desire theirs to be compared.

The facts thus laid before the committee leave them no room for doubt (*a*) that the pass-standards of the College of Preceptors are in many respects inferior to those of the other junior examinations in England; (*b*) that even when measured by the ratio of passes to rejections, *among candidates who offer the subjects required by the Council*, the tests of the college are not so stringent; (*c*) that the average age of

Digitized by Google

the candidates for the college examinations is appreciably less than that of the candidates for the local examinations who offer the subjects required by the Council; (d) that the papers set by the college are in general of a more elementary character.

4. The committee have thought it desirable, in view of the contentions embodied in the statement of the college, to ascertain the views of experienced head-masters in various parts of England who appeared in the published lists as sending in pupils both to the college and to the university local examinations. The names of the head-masters were taken from the College of Preceptors' list in alphabetical order and the grammar and other secondary schools under their charge were so chosen as to be widely distributed throughout the country. A circular letter was issued inviting answers to the following questions:—

(1) In what order would you place the junior locals and the College of Preceptors' second class as regards standard of difficulty, comprehensiveness, time required for preparation, and facility of obtaining distinction?

(2) What is the average age and school-standing (form, class, or the like) of your candidates for the two classes of examinations respectively?

(3) Which do you consider the better and more satisfactory test of a good school education in mathematics, English, Latin, and modern languages?

Some fifty replies were received to about seventy circulars sent out. A few head-masters excused themselves from answering on the ground of insufficient experience of one or other examination; but forty-one sent more or less full answers. The great majority of the head-masters have no hesitation in pronouncing the College of Preceptors' second-class examination to be inferior in standard to the university locals; a small number regard the examinations as "on a par," with more or less of reservation; and only one or two declare it to be superior. As is natural, the answers differ as to details, but the general result is to the mind of the committee conclusive in regard to the point at issue.

5. The answers to the question regarding the age and school-standing of candidates for the respective examinations are less full and complete and contain particulars which might lead to the identification of the schools. But except in the case of "older and duller boys," who take the College of Preceptors' examination because they have failed in or are thought unlikely to pass the local examination, the replies show that in general the candidates for the latter are older and higher in school-standing. This result is in accordance with that deduced from the statistics furnished by the universities and by the college authorities.

6. The recognition for certain purposes of the College of Preceptors' second and third-class examinations by important public bodies is put forward in the statement as implying that these examinations are thereby declared equivalent for all purposes to the other recognised junior examinations. This inference appears to the committee to be untenable. The list published by the Medical Council itself includes a large number of examinations of various grades, from that for a degree in arts downwards, all of which are recognised for the purpose of students' registration. But it cannot be maintained that the Council thereby pronounces these examinations to be equal in standard or regards them as equivalent, except in so far that they all satisfy the *minimum* conditions which it imposes. The fact that the Head-masters' Association includes in its "junior list" all the various "professional preliminary examinations," without distinction, and that the London Technical Education Board and the Education Department include the third division of the College of Preceptors' examination in their recognition, shows that in like manner the lists of these bodies are not constructed on the principle of parity among the examinations referred to. The lists merely indicate that all fulfil certain *minimum* requirements, and, further, that these *minimum* requirements are less stringent than those insisted on by the Council. The inference as to equivalence which the statement suggests is therefore more than doubtful *a priori*. But the committee have thought it desirable to make direct inquiries on the subject and have ascertained definitely that no such inference is authorised or can be maintained. The committee are thus fully justified in affirming that their own view of the argument put forward by the College of Preceptors is that taken by the "independent and unbiassed authorities" concerned.

The committee are for these reasons unable to admit the conclusions of the statement of the College of Preceptors. They are convinced that the present standard of the second-class examination is not sufficiently high for the purposes of the Council and they propose accordingly that its recognition should be withdrawn. Should, however, the authorities of the college see fit to establish a preliminary examination of a standard equal or superior to that of the other junior examinations recognised by the Council, the committee would be prepared to include such an improved examination in the list. The minimum standard required would be intermediate between those of the existing first-class and second-class examinations of the college; and the committee assume that the necessary facilities for inspection granted by other examining bodies and hitherto granted by the college would be continued. Without these facilities the committee would be unable to assure themselves that the required standard was duly established and continuously maintained. The committee accordingly propose to make it a condition of recognition in the case of this and of the analogous examinations in Scotland and Ireland that specimens of the answers sent up by successful candidates should from time to time be submitted for inspection.

II.—The committee do not fail to recognise that the Royal Colleges of Ireland have made a serious effort to improve the character and standard of their preliminary examination. The Examining Board now consists of men of experience and standing in the educational world who are otherwise unconnected with the Colleges. The regulations have been revised so as somewhat to widen the scope of the examination. And it is proposed to raise materially the standard for passing "so as to approximate it to that of the Middle Grade Intermediate Examination." If the design thus outlined should be fully carried out some of the objections which have for long been taken to this examination would be fairly met and the committee would be prepared to assent to the recognition of the new examination, at least until the time arrives when it is possible to arrange in Ireland for a convenient public examination under the auspices of a competent educational authority independent of the licensing corporations. The Intermediate Educational Board of Ireland appears to fulfil this condition. It is in direct relation with the public and other schools and is conversant with the conditions of Irish primary and secondary education, of which it, to a great extent, controls the standards; by its constitution it is calculated to be independent in its judgments; and it possesses the machinery and the means for conducting its examinations with efficiency. The objections raised by the Colleges to the discontinuance of their own examination in favour of those of the Intermediate Education Board practically reduce themselves to two—(1) that the Intermediate examinations are limited to candidates of definite ages and (2) that they are held at a time of the year which is inconvenient to some intending students of medicine. These objections the Board has hitherto not seen its way to meet, apparently on the ground that it lacks the statutory powers to do so. The committee, however, understand that the powers and functions of the Board have been referred to a special commission for consideration and an opportunity is thus afforded for making representations on the subject to those in authority in Ireland. If the Board were prepared to hold in April and September a supplemental examination of a standard approximate to that for middle grade certificates and open to pass candidates without limitation of age, the difficulties put forward by the Royal Colleges would be removed. There would then remain no valid reason against the adoption of the reiterated recommendation of the Council that the Conjoint Preliminary Examination should be discontinued. The committee accordingly recommend that the Council should make a formal representation to the Commissioners on the subject.

III.—The Educational Institute of Scotland, like the Royal Colleges in Ireland, has frankly accepted the decision of the committee that the standard of its preliminary examination was insufficient for the purposes of the Council. Early in the year it announced its intention of issuing new regulations with the object of materially improving the examination and raising its standard. These have now been published. In the opinion of the committee the Preliminary Examination has been much improved by the changes now adopted, and the examination papers submitted are of a more advanced character. Samples of the answers of candidates who just succeeded in passing at the last examination have been submitted and show that an appreciable advance has been made in regard to the *minimum* requirements. There is thus every reason to expect that the method of marking and the pass-standard will prove, on inspection of the results during 1899, to be sufficiently stringent, and the new examination of the Educational Institute will accordingly be entitled to recognition as a junior examination.

IV.—In view of the fact that Malta is within Her Majesty's Dominions the committee are of opinion that it would be more appropriate to give explicit recognition to its University and they accordingly propose to place the University Matriculation Examination on the list with those of the other colonial universities.

V.—The communications from Indian and Colonial Universities have enabled the committee to revise the list with the aid of the latest information on the present character and standard of the examinations it includes. Another communication is from an American University in the Western States and asks that its matriculation examination may be recognised. The particular examination in question does not fulfil the conditions prescribed by the Council and is therefore ineligible for recognition. It has not been the practice of the Council to place any American examinations on its list, though individual students from the United States who were able to present clear evidence as to the character of the Arts Examination they had passed have been repeatedly admitted to registration. The committee propose to take into consideration the question whether a more general recognition might not be extended to certain of the American universities in view of the fact that in recent years a considerable advance has been made in regard to their curriculum and requirements for graduation in medicine. Until, however, the committee have been able to give fuller study to the question thus raised they do not propose to offer any definite recommendations thereon to the Council.

The list of the examinations which in the opinion of the committee fulfil the recently increased requirements of the Council, and which they accordingly think should be recognised for purposes of registration on and after Jan. 1st, 1900, is hereto appended. But in presenting it the committee desire it to be known that they contemplate the early introduction by the Council of a further increase in the stringency of the educational tests to be applied to intending students of medicine.

By the coöperation of the various educational authorities concerned much may be done to raise the standard even of the junior examinations, and a number of these authorities have, at the request of the Council, already undertaken to take measures in this direction. The Council, moreover, by its own action in henceforth requiring another language, in addition to Latin and English to be taken up by students, has materially enlarged the scope of its demands. In these two ways preparation is being made for the transition from the standard of the junior to that of the senior examinations. This transition the committee are desirous of effecting so soon as the educational conditions of the country will permit, but they believe that a gradual and continuous advance along their present lines will be more likely to bring about a substantial improvement in the general education of medical students than any sudden and revolutionary change in the formal requirements of the Council. By exercising steady pressure where necessary on the educational authorities in favour of the adoption of better and more searching methods, by withdrawing recognition from examinations which are proved to have become inefficient, and by careful supervision or inspection of all, the committee believe that they can give material aid in bringing about the desired improvement and they have every reason to expect that their efforts will be supported and confirmed by the Council at large.

LIST OF EXAMINATIONS IN GENERAL EDUCATION TO BE RECOGNISED AS FROM THE 1ST DAY OF JANUARY, 1900.

I.—University Examinations held in the United Kingdom.

University of Oxford.—Junior local examinations (certificate to include all the required subjects at one time). Senior local examinations (certificates to include the required subjects). Responsions (certificate to be supplemented by others showing that the required mathematical subjects have been passed in). Moderations (certificates to include the required subjects). Final examination for a degree in Arts.

University of Cambridge.—Junior local examinations (certificate to

Digitized by Google

include all the required subjects at one time). Senior local examinations (certificates to include the required subjects). Higher local examinations (certificates to include the required subjects). Previous examination (certificates to include the required subjects). General examination (certificates to include the required subjects). Final examination for a degree in Arts.

University of Durham.—Examination for certificate of proficiency (certificate to include all the required subjects at one time). Preliminary examination in Arts for graduation in Medicine and Science (certificate to include the required subjects). Final examination for a degree in Arts.

University of London.—Matriculation examination (certificate to include the required subjects). Final examination for a degree in Arts or Science.

Victoria University.—Preliminary examination (certificate to include all the required subjects at one time). Final examination for a degree in Arts or Science.

University of Wales.—Matriculation examination (certificate to include all the required subjects at one time). Final examination for a degree in Arts.

University of Edinburgh.—Junior local examination (certificate to include all the required subjects at one time). Senior local examination (certificates to include the required subjects). Preliminary examination for graduation in Medicine and Surgery (certificate to include the required subjects). Preliminary examination for graduation in Arts or Science (certificate to include the required subjects). Final examination for a degree in Arts or Science.

University of Aberdeen.—Junior local examination (certificate to include all the required subjects at one time). Senior local examination (certificates to include the required subjects). Preliminary examination for graduation in Medicine and Surgery (certificate to include the required subjects). Preliminary examination for graduation in Arts or Science (certificate to include the required subjects). Final examination for a degree in Arts or Science.

University of Glasgow.—Preliminary examination for graduation in Medicine and Surgery (certificate to include the required subjects). Preliminary examination for graduation in Arts or Science (certificate to include the required subjects). Final examination for a degree in Arts or Science.

University of St. Andrews.—Preliminary examination for graduation in Medicine and Surgery (certificate to include the required subjects). Preliminary examination for graduation in Arts or Science (certificate to include the required subjects). Final examination for a degree in Arts or Science. Final examination for the diploma of L.L.A.

University of Dublin.—Public entrance examination (certificate to include the required subjects). Examination for the first, second, third, or fourth year in Arts (certificate to be signed in the approved form by the medical registrar of the University). Final examination for a degree in Arts.

Royal University of Ireland.—Matriculation examination (certificate to include the required subjects). Final examination for a degree in Arts or Science.

Oxford and Cambridge Schools Examination Board.—Lower certificate (to include all the required subjects at one time). Higher certificate (to include the required subjects).

II.—Government Examinations held in the United Kingdom.

Scotch Education Department.—Examination for lower grade leaving certificate (to include all the required subjects at one time). Examination for higher grade or honours leaving certificate (to include the required subjects).

Intermediate Education Board of Ireland.—Junior or middle grade examination (certificate to include all the required subjects at one time). Senior grade examination (certificates to include the required subjects).

III.—Examinations by Chartered Bodies held in the United Kingdom.

College of Preceptors.—Examination for a first-class certificate (to include all the required subjects at one time).

Educational Institute of Scotland.—Preliminary medical examination (certificate to include all the required subjects at one time).

Royal Colleges of Physicians and Surgeons in Ireland.—Preliminary examinations (certificate to include all the required subjects at one time).

(*** The Council has recommended that this examination be discontinued.)

IV.—Examinations held out of the United Kingdom.

University of Malta.—Matriculation examination.

University of Calcutta.—First examination in Arts.

University of Madras.—First examination in Arts.

University of Bombay.—Matriculation examination.

Panjab University.—Intermediate examination in Arts.

University of Allahabad.—Intermediate examination in Arts.

Ceylon Medical College.—Preliminary examination.

University of McGill College, Montreal.—Matriculation examination.

University of Bishop's College, Montreal.—Matriculation examination.

College of Physicians and Surgeons of the Province of Quebec.—Matriculation examination.

Universities and Colleges of the Province of Ontario.—Departmental Arts matriculation examination (conducted under the direction of the Provincial Education Department).

University of Manitoba.—Preliminary and previous examinations.

University of New Brunswick, Fredericton.—Matriculation examination.

University of Mount Allison College, New Brunswick.—Matriculation examination.

College of Physicians and Surgeons of New Brunswick.—Matriculation examination.

Dalhousie College and University, Halifax, Nova Scotia.—Matriculation examination.

Provincial Medical Board of Nova Scotia.—Preliminary examination.

Newfoundland Medical Board.—Preliminary or matriculation examination.

University of Melbourne.—Matriculation examination.

University of Sydney.—Matriculation examination. First year examination in Arts. Senior public examination. Entrance examination for Medicine and Science.

University of Adelaide.—Senior public examination.

University of Tasmania.—Senior public examination.

University of the Cape of Good Hope.—Matriculation examination.

University of Otago.—Preliminary medical examination.

University of New Zealand.—Preliminary examination for medical students.

Codrington College, Barbados.—Examinations qualifying for a degree in Arts at the University of Durham.

Foreign Universities in Europe.—The German Arbiturienten-Examen of the Gymnasia and Real-gymnasia; examinations entitling to the French diplomas of Bachelier ès Lettres and Bachelier ès Sciences; and other corresponding entrance examinations to foreign universities in Europe.

Egyptian Government.—Examinations for the secondary education certificate.

Sir JOHN BATTY TUKE, chairman of the Educational Committee, in moving the adoption of the report said that he did not intend to enter into detail with reference to its contents, as the report during his continued ill-health had been drafted by Dr. MacAlister, and Dr. MacAlister would make any necessary explanation. He, however, might say a few words as to the general principles which had actuated the Education Committee in drawing up the report. They had been actuated by the very strongest desire to raise the standard of preliminary education in connexion with the medical profession. But the question arose as to how this could be done. At one period of the committee's deliberations they thought that the simplest and best manner in which to place these preliminary examinations would be to cut out all junior examinations, but subsequently they came to the conclusion that any such drastic measure as that without full notice would be premature. Personally he was of opinion that it was to the direct interest of the public that the standard of medical education should be raised. He was also of opinion that the best way of raising the standard of medical education was the raising of the standard of preliminary examination in general knowledge, inasmuch as by establishing a higher standard of preliminary education they would get men sufficiently well trained to enter upon the study of the higher professional subjects. He was further of opinion that it was necessary to gradually approximate the meshes of the net and that they should not by any *per saltum* action complicate the situation so seriously as would have been done had the original proposition been carried out. There was no doubt in his mind that if the original proposition had been persevered in the supply of medical students would have fallen off to such a considerable extent that it would not have been beneficial to the country. As an indication of that they would find in the figures showing the results of examinations, as presented in their minutes for 1897, that the percentage of rejections of candidates for the medical profession was between 24 and 63 per cent. He had not calculated the average, but he felt certain that the percentage of rejections was nearer 50 than 40 per cent. The committee had to meet that. To a considerable extent they believed that they had been able to meet it, as they thought that by steady pressure on the educational bodies they would be able to further improve the preliminary examinations. They trusted that the time was not far off when they should be able to cut off the junior examinations. He did not think it would be a fair thing to cut off these junior examinations until at least five years after the promulgation of this new report by the committee, and until such times as they could see their way to accept none but senior examinations they would do all in their power to raise the standard of the junior examinations. He hoped the Council would support the committee in their effort.

Some conversation followed. Instead of proceeding with Sir John Batty Tuke's motion it was agreed, on the proposal of Dr. MCVAIL, that the Council should go into committee and consider the report. Thereupon it was moved by Sir JOHN BATTY TUKE that the report be approved.

Dr. MACALISTER, in seconding, went over most of the details brought out in the report. He showed that of the various examinations for candidates for the medical profession which were recognised by the Council only three had been called in question—the College of Preceptors' second-class examination in England; the examination of the Educational Institute of Scotland; and the examination of the Conjoint Board for Ireland. While the two latter had shown an appreciable readiness to meet the Council's requirements the College of Preceptors had challenged the finding of the Council that their second-class examination was inferior. But after a long and exhaustive inquiry, as the committee's report showed, the committee were forced to the conclusion that the examination in question was inferior to the lowest requirement of the Council—the University junior local

Digitized by Google

examinations. The college endeavoured to show that their results were superior to those obtained in the local examinations, but in the attempt they selected a fallacious basis, and the fact really was that the results were the reverse of what the college authorities represented them to be. He proceeded to express satisfaction with the course adopted by the Educational Institute of Scotland and the Conjoint Board for Ireland and jocularly suggested that the time was opportune for drawing closer the bonds between this country and the United States in regard to American entrance examinations which the medical authorities of this country had never yet recognised. They might see whether examinations of some of the American universities were not up to the Council's standard, and the committee proposed to get information on the subject. As to the future he was one of those who thought that the Council should require a standard of preliminary examination considerably higher than the junior examination of the present day—an examination which might be effectively described as a senior rather than a junior examination. Junior examinations at present practically represented nine-tenths of the medical students. The Council certainly could not at once take the step of doing away with these junior examinations, but he hoped that it would be possible for them, within the five years referred to by Sir John Batty Tuke, to adopt the standard which was now known as "senior."

Sir RICHARD THORNE, who also favoured the view that candidates for the medical profession should be required to pass the "senior" examination, questioned whether the head-masters who had given their opinion as to the relative value of the examination and the College of Preceptors and the university "locals" had not been misled by the way in which the case had been stated to them. Supposing they had not, what he wished to contend was that the difference between 30 per cent. of passes or rejections in the "locals" with 33 in the College of Preceptors' examinations, or *vice versâ*, was practically *nil*, so far as the Council's idea went of securing a higher and uniform standard. The university junior examination ought to go with the examination of the College of Preceptors. The boys who passed these "locals" were in the majority of cases under fifteen years of age. It was not the intention of the Council that boys under sixteen years should be accepted as candidates for entrance to the medical profession, and these junior examinations did not produce youths of that age. The "senior" examinations did, for he believed he was absolutely correct in saying that the average age of candidates who passed the two senior examinations was sixteen and a half years. That was practically the age they were aiming at and these two senior examinations gave boys of the training and age that were wanted. They could not at once do away with the junior examinations they had agreed to accept as sufficient, but he should like the Council to agree with the view that after the expiration of the next five years they should not accept any of these junior examinations at all.

On the motion of Dr. LEECH the debate was adjourned and the Council resumed.

Commissions in the Navy.

A table of figures showing results of competitions held on Oct. 31st last for commissions in the medical department of the Royal Navy was received and entered on the minutes and thanks were given to the Director-General of the department for furnishing the information contained in it.

Registration Fees.

Dr. LITTLE, with the consent of the seconder, Dr. ATTHILL, obtained leave to withdraw from the programme of business a notice of motion to propose "That on and after Jan. 1st, 1899, a fee of 10*s.* be charged by the registrars of the Branch Councils to every person applying to be registered as a medical student."

The Council adjourned.

TUESDAY, NOV. 29TH.

The Council met again to-day and resumed work, Sir WILLIAM TURNER being in the chair.

The Preliminary Examinations.

The Council went into committee of the whole Council and proceeded with the consideration of the report of the Education Committee with regard to the revision of the list of recognised preliminary examinations.

Dr. LEECH said that the last paragraph of the report was not so satisfactory as he could wish. It seemed to him to be an incentive to those who conduct the junior examinations to raise the standard of those examinations and so keep them on the list. Now he thought it should be distinctly understood that within a certain time these examinations were to be removed from the list. He was sure all the members of that Council felt that it was impossible to raise them to a proper position. It had been suggested that by removing them from the list they might injure the public but he failed to see that the number of students would be limited. His impression was that they would get a better set of men, and that men who at present were only half educated would be properly educated. He suggested that the Education Committee should consider whether it might not be desirable to strike off all the junior examinations in five years.

Sir DYCE DUCKWORTH said he must express his personal disappointment with this report. He had hoped the committee would have seen its way to a much stronger report in which the entrance examinations to their profession were considerably tightened. It was little short of a scandal that these examinations should be so easy. He thought it would be for the benefit of the scholastic profession as well as for those who were going to enter upon the study of medicine that that Council should put down some decided time limit for these junior examinations. If a limit were fixed then the schools would work up their pupils to the required standard.

Sir CHRISTOPHER NIXON bore testimony to the great care and pains which the Education Committee had bestowed upon this work. He knew nothing about the College of Preceptors, not even where it was situated, but it seemed to him from the report that its junior examination was not up to the required standard. That was proved by the statistics and by the examination papers and by the independent and unbiased opinion of 35 of the head-masters of various public schools. On this last point he might say that he did not see the force of the objection raised by Sir Richard Thorne as to the reports of these head-masters. These gentlemen were made aware of the question at issue.

Sir RICHARD THORNE said that since speaking yesterday he had seen the covering letter sent with the inquiry and he was bound to admit that his inference was not justified.

Sir CHRISTOPHER NIXON said he was glad to hear this from Sir Richard Thorne. As to the conjoint examination of the Royal Colleges in Ireland he might say that it was the strong opinion of the Committee of Management that it would be desirable to have a preliminary examination conducted by a body not connected in any way with the professional colleges, and he hoped that the Council would take a very strong part in recommending the establishment of an examination by the Intermediate Education Board which would be suitable to the wants of medical students. Of one thing the Council might be sure and that was that so long as the conjoint examination continued it would be the endeavour of the Royal Colleges to maintain in it a high standard.

Mr. CARTER said he hoped that the Council would stiffen its back in connexion with this matter and that its resolution would strengthen the hands of the committee to the extent of enabling a definite time to be fixed, after which the junior examinations would not be recognised. By giving sufficient notice neither the teachers nor the students would be taken by surprise.

Mr. TICHBORNE said that the body he represented, the Apothecaries' Hall of Dublin, had given up its preliminary examination and he would like to get an assurance from the representatives of the Royal Colleges in Ireland that in the event of the Intermediate Education Board establishing an examination they would discontinue their conjoint examination.

Dr. ATTHILL replied that he had no hesitation in giving an assurance on behalf of the Royal College of Physicians of Ireland provided that the new examination met the requirements of the Council and was suitable as to age and dates and standard.

Sir PHILIP SMYLY gave a similar assurance on behalf of the Royal College of Surgeons in Ireland.

Mr. BROWN said he was disappointed that the report did not go further. He was sorry that the committee had not seen their way to strike off the list the junior examinations of Oxford and Cambridge, which appeared to him to be little superior to the junior examination of the College of Preceptors. On the previous day a medical practitioner of some standing told him that he passed the Cambridge examination at the age of thirteen years.

Digitized by Google

Sir WILLIAM THOMSON suggested that three or at the most four years' notice should be given of the higher standard. As to the Royal Colleges in Ireland he assured the Council that both bodies were most anxious to see an examination established by an independent authority.

Dr. MCVAIL submitted that the Council was now in a position to fix a date and he would be prepared to move :—

That the transition from the standard of the junior to that of the senior examinations which the Education Committee in their report recommend shall take effect from Jan. 1st, 1905.

The PRESIDENT said that the following motion had been put into his hands by Dr. Leech, namely :—

That the Education Committee be requested to consider and report to the Council during the next session as to the earliest date at which, in their opinion, it will be practicable to raise the minimum requirements of the Council as regards preliminary examinations to the standard of the senior and higher grade examinations at present recognised.

Dr. PETTIGREW said he was quite convinced of the need for raising the standard, but he had some difficulty as to when and how it should be raised. Education must precede examination and in Scotland secondary education was not in a satisfactory state, and he held that time would require to be allowed in order that secondary education might be improved.

Dr. HERON WATSON thought this was clearly a case for reasonable warning being given.

Dr. MACALISTER read to the Council the covering letter sent to the head-masters which, he said, put the whole question at issue before them. With reference to the College of Preceptors it would be remembered that he said that the college made a certain claim with reference to the action of the Education Department. That claim was challenged. He had seen the Vice-President of the Council who had authorised him to read the following letter, viz. :—

Adverting to your letter dated the 27th inst. I am directed to state that you are right in supposing that the recognition by the Education Department of the second-class certificate examination of the College of Preceptors as practically equivalent to the third-year examination prescribed under the code for pupil teachers does not imply that the examination is of equal standard and range for all purposes with the Oxford and Cambridge junior local examinations which are similarly recognised for candidates desiring to be apprenticed for one year as pupil teachers.

In the list of recognised examinations there was a mistake under the heading of the Victoria University ; the entry should read : "Preliminary examinations (certificate to include the required subjects)."

Dr. LEECH then formally moved the adoption of the motion read by the President and Dr. LITTLE seconded the motion.

Sir J. BATTY TUKE and Dr. MACALISTER recommended the Council to accept the motion.

Dr. MCVAIL said that in view of the action of the chairman of the committee he would not press his motion but he would propose it again if within a reasonable time the committee did not bring forward a definite time limit.

The report was then adopted and the motion of Dr. Leech became the finding of the Council.

The Council went out of committee and approved the proceedings in committee of the whole Council.

The Examination of the Apothecaries' Hall of Dublin.

Sir DYCE DUCKWORTH brought up reports by the Examination Committee on two examinations held by the Apothecaries' Hall of Dublin.

Mr. TICHBORNE gave explanation with regard to certain criticisms passed by the committee in these reports.

Sir RICHARD THORNE commented on observations made by the inspector with regard to over-marking.

Both reports were approved by the Council.

Midwives Bill.

On the motion of Dr. MACALISTER the Council entered on the minutes a report by the committee appointed by the General Medical Council on May 25th last to confer with delegates from a committee of the promoters of the Midwives Bill, together with an appendix containing a report of the proceedings at the conference on June 25th last. The Council agreed to go into committee on the report, which contained the following :—

The sixth point set out by the delegates relates to the expenses of carrying out the Act. The delegates point out that since their Bill is a private members' Bill they cannot insert a clause providing for any payments out of the exchequer. This, doubtless, is so. But whatever the remedy may be it seems quite clear that the cost of carrying out the provisions of any such legislation, however desirable that legislation may be in the interests of certain portions of the community, ought not to be paid out of the funds of the General Medical Council. The advantages accruing from such legislation will primarily concern the public and the licensed midwives, whereas no one can suggest that it will pecuniarily benefit the medical and dental professions, who by payments on registering their diplomas provide the only funds which are at present at the disposal of the Council.

Your committee have reason to believe that the Lord President of the Council is desirous of receiving some expression of opinion from the Council as to how this matter may best be met ; and they would therefore make the following proposals to the Council :—

1. That the duty of fulfilling any duties that may be imposed upon the Council under an Act regulating the practice of midwives be delegated to a special committee after the precedent followed in the case of the Dental Committee.

2. That so long as any such Act is only made to apply to England and Wales the Special Committee consist of five members of the English Branch Council.

3. That, in the first instance, the Special Committee meet in London twice a year.

4. That the fees, &c., for attendance on this Special Committee be the same as those paid to the members of the Executive and Dental Committees.

Sir RICHARD THORNE, as chairman of the committee, asked that the report, which he said had been circulated two months ago, should be held as read. There was one point in connexion with it that he thought he must draw attention to—namely, the expense of carrying out any Act regulating the practice of midwives. He had received an intimation from the Government that if any expense was likely to be involved by the General Medical Council in carrying out such an Act they should state what they thought it would be before the Civil Service estimates were made up for the year from March next. In reply he had made it clear that the fees which were paid by dental and medical students to the General Medical Council could not be used for carrying out an Act relating to midwives and any expense incurred must be paid from a grant by the Government. He proceeded to show that the grant must not be less than £300 a year and concluded by moving the adoption of so much of the report as preceded the recommendations.

Dr. LOMBE ATTHILL, in seconding the proposal, said that if any Midwives Act applied to Ireland there should be at least one representative of that country on the committee.

Sir W. THOMSON and Mr. HORSLEY expressed the view that the estimate of the expenditure under such an Act as that in question was too low.

The PRESIDENT thought the Council should leave it to Sir Richard Thorne and himself to arrange about the matter.

Dr. LOMBE ATTHILL thought there might be appeals from the Midwives' Board against regulations of the Council, and if the Council had to spend, say, a day in debating any one of those they ought to be paid therefor.

Dr. GLOVER was of opinion that the expression of this view came too late, seeing that the Council without remuneration had been discussing the midwives question for the last ten or twelve years.

Sir W. GAIRDNER did not want to intervene in regard to this financial question. What he wished to say was that the result of reading the report before them made him very desirous that the special committee proposed would be a strong committee that would hold well to the principles which the Council had laid down. He could not read the report of the conference between their committee and the promoters' delegates without feeling that the Council were to be opposed tooth and nail. The delegates said they would accept in the abstract the licensing of midwives instead of their registration, but then would they not try to get the Council's licensing proposal defeated in Parliament, so that the resolution of the Council, which went towards the suppression of incompetent, ignorant, and bad characters, would come to naught? It seemed to him that there was a deliberate intention and attempt to keep up the "Gamp"—an attempt to protect the "Gamp." Although the delegates did not say that they were going to oppose the Council's proposal in Parliament he believed they would do it.

Mr. BROWN thought that Sir W. Gairdner had called attention to a point which was exceedingly important. Where should they be if they accepted this report? Having read twelve of the forty-eight pages of which it consisted he thought he was far in advance of other members of the Council on the subject.

The PRESIDENT : The report was circulated weeks ago.

Sir RICHARD THORNE : At least two months ago.

The PRESIDENT : Then, Mr. Brown, if you have not read the whole of the report it is not because the committee did not give you opportunity.

Mr. BROWN : There are members who have not read it at all.

The PRESIDENT : Speak for yourself.

Digitized by Google

Mr. BROWN: Well, I prefer that the old committee—the committee on the subject that existed before this Conference Committee—should be reappointed with instructions to watch any legislation which may be proposed early next year and take any necessary action to bring the matter before the Council.

Sir RICHARD THORNE said that the Conference Committee ceased to exist when the conference was over. He should not stand in the way of the reappointment of the previous committee.

Dr. MACALISTER urged that they ought to deal with the four recommendations of the committee before they proceeded to consider the question of reappointment of the conference or other committee.

The motion to adopt the non-contentious part of the report was then agreed to.

Sir RICHARD THORNE thereupon moved a modification of recommendation 1—namely:—

That the duty of fulfilling any functions that may be imposed upon the Council under an Act regulating the practice of midwives be delegated to a special committee and that the committee report to the Council.

Dr. LOMBE ATTHILL seconded and the motion was agreed to.

Sir RICHARD THORNE next moved:—

That so long as any such Act is only made to apply to England and Wales the special committee consist of five members of the English Branch Council.

Dr. ATTHILL, in seconding, remarked that it might be as well to inform the Lord President of the Privy Council that the expenses required would be greater if the Act was extended to Ireland.

The PRESIDENT explained that that could be stated in a covering letter.

The motion was agreed to.

Sir RICHARD THORNE further moved:—

That in the first instance the special committee meet in London at least twice a year.

Dr. MACALISTER reminded the Council that what this committee would have to do would simply be to approve of the rules made by the Midwives Board. Their duties for the first year would be heaviest. After the first year there would be nothing to do for a long time.

The motion was agreed to.

Sir RICHARD THORNE, accepting a suggestion made by Mr. Horsley, next moved:—

That the sum allowed by the Treasury to the General Medical Council for the performance of any duties imposed upon it under an Act regulating the practice of midwives should, in the opinion of the Council, be adequate to cover both the general and special expenses of the Council and its special committee.

Mr. HORSLEY seconded and the motion was also agreed to.

The Council resumed and the report of proceedings in committee was adopted.

Mr. BROWN moved for a committee to watch proceedings on the midwives question in the forthcoming session of Parliament.

Discussion followed and ultimately, on the motion of Mr. BRYANT, seconded by Mr. TEALE, it was agreed to reappoint for the purpose just mentioned, the Conference Committee, consisting of Sir Richard Thorne, Dr. Glover, Dr. MacAlister, and Sir Christopher Nixon, with Mr. Horsley as an additional member.

In the course of the discussion Dr. MCVAIL had remarked that he did not want any Scotchman to be on the committee.

Thereupon the PRESIDENT pointed out that Dr. MacAlister, who was a Scotchman, had been named.

Dr. MCVAIL indicated that he did not object to the Cambridge Professor's appointment as, he said, all the Scotch was out of Dr. MacAlister long ago.

Registration of Medical, Surgical, and Dental Companies.

The Council next received a report from the committee on amendments to the Companies Acts which was in the following terms:—

At the meeting of the General Medical Council, May 30th, 1898, the following resolution, which had been arrived at *in camerâ* on May 28th, was placed upon the minutes:—

"That the President, Mr. Tomes, and Mr. Horsley be a committee to take such steps as they deem most effective to induce the Government to insert a clause in the Companies Act Amendment Bill, now before Parliament, with the object of preventing the registration of companies to carry on medical, surgical, and dental practice."

The committee was appointed in consequence of information brought before the Council by Mr. Tichborne that a drug company in Cork, registered under the Companies Act, had intimated that one of its objects was to carry on the business of physicians and surgeons. It was also pointed out to the Council that encroachments on the practice of other professions and businesses for the legal pursuance of which a personal qualification was necessary were being conducted under cover of the Companies Acts. The attention of a departmental committee of the Board of Trade, sitting under the presidency of Lord Davey, had been called some time previously by the British Medical Association, the British Dental Association, the Medical Defence Union, the Royal College of Veterinary Surgeons, and the Pharmaceutical Society, to the nature of these infringements of professional Acts, but that committee was of opinion that the matters complained of did not properly fall within the scope of the terms of the reference made to them by the Board of Trade. They expressed, however, in their report the hope that one of the clauses of the Bill which they had drafted might have some effect in providing a remedy.

The acknowledgment by a Government committee that a grievance existed was an important step gained and the bodies named approached Lord Herschell with the view of obtaining his assistance in introducing an amendment in the Companies Act Amendment Bill, which was then being brought by the Government before the House of Lords. There was reason to believe that the Board of Trade would not oppose Lord Herschell's amendment, but as the Government Bill was shelved for a time by being referred to a select committee of the House of Lords the matter has not been further proceeded with.

The committee of the General Medical Council attempted, in the first instance, to prevail upon the Board of Trade to take up the question in its relations to the medical profession. A deputation consisting of Sir Dyce Duckworth, the senior treasurer (in the absence of the President from town), Mr. Horsley, and Mr. Tomes, accompanied by Mr. Muir Mackenzie, waited upon the President of the Board of Trade, with whom was Mr. Smith, C.B., and submitted a memorial to him on the subject. Sir Wm. Priestley, M.P., was also present. Mr. Ritchie expressed himself in general terms as perfectly friendly to the objects of the deputation, but was of opinion that the remedy for the grievance complained of was to be found elsewhere than in the proposed Companies Bill, so that he was unwilling to take any steps in the matter.

Moreover, the chances of any Companies Act Amendment Bill becoming law within a reasonable length of time appeared uncertain, and it hence seemed to be expedient to make attempts in some other direction.

Accordingly, Sir Kenneth Muir Mackenzie, the private secretary to the Lord Chancellor, was waited upon and requested to lay a memorial in substance much the same as that which had been submitted to the Board of Trade before his Lordship.

Very shortly after this, on the occasion of a Pharmacy Bill, which had passed the House of Commons, coming before the House of Lords, the Lord Chancellor introduced an amendment which dealt with the question so far as pharmacy was concerned, and this amendment met with the support in principle at all events, of Lord Herschell. But this Pharmacy Bill had passed by agreement through the House of Commons as a practically unopposed measure, and for that, and possibly other reasons, the amendment was withdrawn by the Lord Chancellor, who, however, intimated in withdrawing it that the matter would be subsequently dealt with in another form. This committee were advised to have a draft of a Bill prepared, which in our opinion would meet the difficulty in the case of the Medical and the Dentists' Acts, and they accordingly requested the standing counsel to the General Medical Council, Mr. Muir Mackenzie, to do this in order that it might be submitted to the Lord Chancellor. This has now been done. The committee ask the Council to approve of their action.

Mr. TOMES, in moving the adoption of the report, said that it was brief in relation to the importance of the subject. There was a reason for that. A good deal of the work of the committee had fallen to be done in a conversational manner with officials of departments of the Government, and the members of Council must know that if they had interviews with officials of practically a private nature and then went and proclaimed the whole upon the housetops the officials involved would not afterwards speak so freely as they had done previously. There had been a good many more interviews than were mentioned in the report, and the chairman and the other two members of committee would be exceedingly pleased to give a good deal of information to any member of the Council who might ask them privately for it. The committee had very good hopes of accomplishing what they were appointed to do. They had made, he thought, very real progress in the matter. If they looked at the end of the report they would see that the committee were required to have a Bill on the subject drafted. It might possibly surprise some members of the Council that the draft Bill did not appear in the report, but there were a good many reasons for not producing this draft Bill. The Council were not promoting the Bill. The draft Bill was only a suggestion to be placed before the Lord Chancellor to let him see what the committee thought would be effective on the subject. The Lord Chancellor might not adopt that draft Bill or a single phrase of it. The committee did not produce it, for if they did it would give an opportunity to anyone who learned what its contents were to start opposition. A copy of the proposed measure lay in the offices of the Council and it could be inspected by any member of Council. He asked that all the members of Council should inspect it and assist the committee in getting it passed into law. The committee asked the Council to approve of their action because there was a little change of front in their attitude. They were appointed to get the Government to insert a clause in the

Digitized by Google

Companies Bill, but they had taken it upon themselves to change their commission and had approached the Lord Chancellor instead with a new Bill. The committee must ask pardon of the Council for departing from what they were appointed to do. If reappointed they would endeavour to get a Bill that would be efficient. They had to deal with a class of people who were trying all they knew and employed all the legal acumen they could get to evade the law, and they must really endeavour to get a stringent Act. The evil complained of was not disappearing. No less than three cases had been heard of since they sent their memorial to the Lord Chancellor and they must use their best endeavour to check the evil.

Mr. TICHBORNE, as the initiator of the movement in the Council, endorsed everything which had been said, but he wanted to know if there would be any difficulty in considering this secret Bill in the Council so that all the members might know what it meant. It was so far good to say that they could see it in the office, but they ought to have an opportunity of discussing it and making suggestions.

Mr. TOMES said that the Council were not promoting the Bill. The draft which had been handed to the Lord Chancellor was simply a suggestion for a Bill.

Sir W. THOMSON said that the suggestion was that of three members of the Council. Was there any objection to the whole Council knowing what the suggestion was? Why should they not go *in camerâ* for ten minutes to learn what it was?

The PRESIDENT saw no objection to their so doing.

Strangers were thereupon asked to withdraw. On their readmission the PRESIDENT informed them that the committee's report had been approved by the Council.

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, it was then agreed that the committee should be reappointed and should be requested to continue its efforts for the improvement of the law on the subject of companies formed to carry on professional functions. At the suggestion of Dr. MCVAIL and Dr. BRUCE Mr. Tichborne was added to committee.

The Public Health Diploma.

The next business on the programme was the receipt of a report from the Public Health Committee in regard to Sir William Gairdner's motion as to apparent diversities of interpretation given at different places to the regulations of the General Medical Council as regards the course of study for a diploma in public health. This report was presented by Sir Richard Thorne, chairman of the Public Health Committee, and was as follows:—

Your committee beg leave to report that, in pursuance of the resolution of the Council of May 31st, 1898, to the effect that the question of the "interpretation given at different places to the regulations of the General Medical Council as regards the course of study for the diploma of public health," especially in the matter of "the study of the duties of outdoor sanitary work," be remitted to the Public Health Committee, they issued a circular letter on July 7th, 1898, to all the licensing bodies in the United Kingdom which grant degrees or diplomas in public health requesting information on the following points:—(1) The number of certificates as to outdoor sanitary work received during the two years ending June 30th, 1898; (2) the names of the certifying medical officers of health and the number of certificates given by each such officer; and (3) the existence of any rules as to the nature and duration of the tuition determining whether a certificate shall be accepted or not.

The first answers received were in a number of instances such as to involve further correspondence, and it was only during the course of this month that your committee were in possession of sufficient information to enable them to prepare a "summary of answers."

These answers disclose the fact that there exists an almost entire absence of uniformity as regards the interpretation which the different licensing bodies place upon the Regulation of the Council adopted on June 9th, 1896, to the effect that—"Every candidate shall have produced evidence that, during a period of six months after obtaining a registrable qualification, he has practically studied the duties of outdoor work" under a medical officer of health.

Indeed, on one point only do the requirements of the different licensing bodies appear to be alike—namely, in the circumstance that in none of them is it laid down as necessary that the whole of a period of six months shall be devoted to the study of outdoor sanitary work.

Incidentally these answers further disclose the fact that the six months' study of outdoor sanitary work is, in the case of nearly all, if not of all, the licensing bodies allowed more or less to overlap in point of time with the period of six months during which the candidate is further required, under the regulations of the Council, to submit evidence of having "attended during six months practical instruction in a laboratory or laboratories ..... in which chemistry, bacteriology, and the pathology of the diseases of animals transmissible to man are taught."

Several important questions are thus raised as to the interpretation which, in the opinion of the Council, should be placed on their Regulations as to these two six-months' periods of study, in connexion with the antecedent Regulation that "a period of not less than twelve months shall elapse between the attainment of a registrable qualification in medicine, surgery, and midwifery, and the admission of the candidate o any examination or any part thereof for a diploma in sanitary sc ence, public health, or State medicine"

Your committee are not aware how far it was the desire of the Council that they should report to the Council on all the matters which are involved in this question; but if such was the intention of the Council your committee beg leave to suggest that, having regard to the brief interval which has elapsed since the date when they received full information in answer to their circular letter, the matter be referred to them again for further consideration and report.

Sir RICHARD THORNE said that the real effect of this report was to ask whether the Council desired the committee to inquire into the whole question of what students were to do during the six months they were bound to give up laboratory work for outdoor work.

Sir W. GAIRDNER considered that the report of the committee amply justified him in raising the question on its merits.

On the suggestion of the PRESIDENT the report was received as an interim report and the committee was reappointed.

An American Doctoress.

Sir DYCE DUCKWORTH presented the usual report of the Students' Registration Committee on exceptional cases.

Mr. HORSLEY objected to the committee's recommendation that Mrs. Hester S. A. Davies, who had graduated in medicine at the University of Michigan, after passing in June, 1893, a preliminary examination in which all the General Medical Council's subjects were included, should be registered without further preliminary examination on the production of the medical diploma she had obtained from the University of Michigan.

After some conversation the objection was given effect to, and the report was adopted minus the paragraph relating to Mrs. Davies.

Slaughter of the Innocents.

The PRESIDENT, with the view of terminating the session on Wednesday, asked if anything in "the bulky volume of programme" still before them could be dropped.

Dr. GLOVER: Oh, we have come to the slaughter of the innocents.

The PRESIDENT thought that consideration of the memorandum on reciprocity and the statement of the position of foreign practitioners in the United Kingdom was one subject which might be deferred till next May.

Mr. HORSLEY was quite willing to withdraw his notice of motion to propose:—

That a committee be appointed to report upon means to secure identification of registered medical and dental practitioners and to prevent fraudulant personation of such practitioners.

Mr. BRYANT declined to give up his right to proceed this session with a motion for the creation of a sinking fund to enable the Council to repay to the English Branch Council the sum of £25,000 advanced for the purchase of the freehold and the erection of the Council's present offices.

As it seemed useless to try to further reduce the programme the Council adjourned.

WEDNESDAY, NOV. 30TH.

The Council met again to-day with some hope of being able to conclude the business of the session. In this, however, members were disappointed for when 6 o'clock arrived it was found that less than half the remaining business had been disposed of. The Council received and approved a report by the president and treasurers on the proposed alterations in the buildings, postponed until next session the consideration of the amended statement as to the position of foreign practitioners in the United Kingdom, adopted a new form of Standing Order with regard to procedure in the case of practitioners convicted of felony, misdemeanour, crime, or offence, discussed and approved the report of the Pharmacopœia Committee, and devoted some hours to the consideration *in camerâ* of certain legal questions. Our detailed report of the proceedings on this day and on the following day will be published in THE LANCET of next week.

WE have received the following communication from Mr. Victor Horsley, F.R.S., and MR. George Brown, for publication:—

Nov. 30th, 1898.

WE, the undersigned, hereby enter our protest against the legal advisers of the General Medical Council appearing on behalf of the Council in the appeal case now pending in support of the conviction of the late Mr. Herbert Kingsley Hunter for describing himself as a physician.

GEORGE BROWN.
VICTOR HORSLEY.

Medical News.

UNIVERSITY OF LONDON.—At the M.B. examination in October the following candidates were successful:—

First Division.—Charles William Buckley, St. Mary's Hospital; H. Minnie Castledine, B.Sc., Royal Free Hospital; Frederick Fenn Elwes, Middlesex Hospital; Joseph George Emanuel, B.Sc., Mason College and Queen's and General Hospitals, Birmingham; Hugh Fitz-Neville Hine, Middlesex Hospital; Thomas Jeeves Horder, B.Sc., St. Bartholomew's Hospital; Hubert Innes, London Hospital; Henry Gwynne Lawrence and Francis Seymour Lloyd, St. Mary's Hospital; David Nunes Nabarro, B.Sc., University College; and William Bird Herapath Wood, Queen's and General Hospitals, Birmingham.

Second Division.—William Maurice Anderson, London Hospital; Joseph Ashton, St. Mary's Hospital; Henry Thompson Barron, Westminster Hospital; Sydney Henning Belfrage, St. Thomas's Hospital and University College; James William Huxtable Bendle, St. Mary's Hospital; Thomas Percival Berry, Guy's Hospital; George Playne Bletchly, Middlesex Hospital; Elizabeth Honor Bone, Royal Free Hospital; Gabrielle Ruth Slater Breeze, London School of Medicine and Royal Free Hospital; Frank Brickwell, St. Bartholomew's Hospital; Frank Butterfield, Owens College and Manchester Royal Infirmary; Victor Evelyn Collins, Guy's Hospital; Mabel Eliza Cousins, Royal Free Hospital; Harold Arthur Thomas Fairbank, Charing-cross Hospital; Lucinda Catherine E. Forster, Royal Free Hospital; Gerald Dudley Freer, Queen's and Mason Colleges and St. Bartholomew's Hospital; Arthur Brownfield Fry, London Hospital; Leonard Gilbert, St. Thomas's Hospital; John Abel Glover, Guy's Hospital; Arthur Stanley Green, Royal College of Surgeons of Ireland and Meath Hospital; William Layard Griffiths, B.Sc., University College; John Grimshaw, London Hospital; Solomon Gross, Yorkshire College and General Infirmary, Leeds; Joseph Percy Hall, Owens College and Manchester Royal Infirmary; Lionel Edwin Charles Handson, Guy's Hospital; Harry Edward Hewitt, St. Thomas's Hospital; John Howell, Guy's Hospital; Robert Craske Leaning, Frank Charles Lewis, and Colin Dunrod Lindsey, St. Mary's Hospital; John Preston Maxwell, St. Bartholomew's Hospital; Percy William Moore and Donald John Munro, Guy's Hospital; Henry Peet, Yorkshire College; Arthur George Grant Plumley, Medical School and University College, Bristol, and Guy's Hospital; Charles Stanford Read, University College; Francis Riley, Westminster Hospital; Adeline Mary Roberts, London School of Medicine and Royal Free Hospital; Penry William Rowland, St. Bartholomew's Hospital; Claude Rundle, St. Mary's Hospital; Harold Alfred Schölberg, St. Bartholomew's Hospital; Harold Douglas Singer, St. Thomas's Hospital; Cuthbert Allen Sprawson, King's College; Russell Henry Jocelyn Swan, Guy's Hospital; George Padgett Tayler, St. Bartholomew's Hospital; Walter Henry Maxwell Telling, Guy's Hospital; Charles Joseph Utley, Owens College; and Archibald Young, University College, Sheffield, and London.

FOREIGN UNIVERSITY INTELLIGENCE.—*Breslau:* Several of the restrictions to which female medical students have hitherto been subject are now being relaxed.—*Liége:* Dr. Henrijean has been appointed Professor of Pharmacology and General Therapeutics. Dr. Troisfontaines has been appointed to the chair of Special Surgical Pathology.—*Moscow:* Dr. Martinoff has been recognised as *privat-docent* of Surgical Diagnosis.—*Rostock:* Dr. O. Nasse, Director of the Pharmacological and Chemico-Physiological Institute, has been obliged to resign on account of ill-health.

THE SENTENCE ON JOHN LLOYD WHITMARSH.—The Press Association states that the Home Secretary has decided to treat the sentence of the convict Whitmarsh as one of twelve years' penal servitude.

HOSPITAL SUNDAY IN PLYMOUTH.—Oct. 30th was observed in Plymouth as Hospital Sunday and over £600 were collected in aid of the funds of the South Devon and East Cornwall Hospital.

ELECTRIC SHOCKS AT CARDIFF.—Several persons received electric shocks in Wood-street, Cardiff, on Nov. 24th. The explanation given by the electrical engineer was that there were leakages in one or two of the electric light connexions.

BARRY ACCIDENT HOSPITAL.—The hospital committee of the Barry District Council has decided to recommend the council to take over the management of the accident hospital which will be relinquished by the nursing association at the end of the present year.

DEVONPORT SCHOOL BOARD.—The members of the Devonport School Board on Nov. 21st elected Mr. John Rolston, M.D., L.R.C.S. Edin., to fill the first vacancy which has occurred since the present board has been in office. Dr. Rolston has now been for over twenty-five years associated with the Devonport School Board.

THE WATER-SUPPLY OF LLANELLY.—At the meeting of the Waterworks Committee of the Llanelly Borough Council held on Nov. 25th it was decided to erect a second storage reservoir. It will be constructed above the present one at Owmlliedi and will have a capacity of 180,000,000 gallons.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ACLAND, H. T. D., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.

AMBROSE, W. C., B.A. Camb., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital.

ANGIVEN, S. L., M.B. Melb., has been appointed Medical Officer of Health for the St. Arnaud Borough, Victoria, Australia.

ARNOLD, G. J., F.R.C.S., L.R.C.P., has been appointed Clinical Assistant in the X Ray Department at St. Thomas's Hospital.

BARNES, J. A., L.R.C.P., M.R.C.S., has been re-appointed Assistant House Surgeon to St. Thomas's Hospital.

BELGRAVE, T. B., M.D. Edin., M.R.C.S., has been appointed Health Officer for Bulong, Western Australia, vice S. Herriott, resigned.

BELL, R. H., B.A., M.B., B.C. Camb., L.R.C.P., M.R.C.S., has been appointed Junior Obstetric House Physician to St. Thomas's Hospital.

BENNETT, F. A., M.D. Aberd., Ch.M., has been appointed a Physician for Diseases of the Skin, Prince Alfred Hospital, Sydney, New South Wales.

BILL, J. F., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed an Assistant Medical Officer for the Infirmary of the Lewisham Union.

BINGHAM, S. O., L.R.C.P., M.R.C.S., has been re-appointed Assistant House Surgeon to St. Thomas's Hospital.

BOUSFIELD, EDWARD C., L.R.C.P. Lond., M.R.C.S., has been appointed Bacteriologist for the Parish of Camberwell.

BRINDLEY, A. E., M.D. Lond., B.Sc. Vict., has been appointed Medical Officer of Health for Bury, vice W. J. Howarth.

BUTLER, H. J., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the Seventh Sanitary District of the Bradford (Yorks) Union.

BUZZARD, E. F., B.A., M.B., B.Ch. Oxon., has been re-appointed House Physician to St. Thomas's Hospital.

CAHILL, THOMAS, M.D., Ch.M. Irel., has been appointed a Member of the Dentistry Board of Examiners, Wellington, New Zealand.

CHARLES, J. R., B.A., M.B., B.C. Camb., L.R.C.P., M.R.C.S., has been re-appointed House Physician to St. Thomas's Hospital.

COBB, E. H., L.R.C.P., M.R.C.S., has been re-appointed House Surgeon to St. Thomas's Hospital.

COLLINS, W. E., M.B. Lond., M.R.C.S., has been appointed a Member of the Dentistry Board of Examiners, Wellington, New Zealand.

CONNOR, S., M.D., Ch.B. Irel., has been appointed Officer of Health for the Wannon Shire, Nareen Riding, Victoria, Australia, vice W. D. K. Macgillivray, resigned.

FRIDAY (9th).—WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. J. B. Ball: Methods of Examining the Throat and Nose.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

OYSTERS.

To the Editors of THE LANCET.

SIRS,—Will any of your correspondents kindly say what kind of oysters can now be recommended without fear of typhoid fever?

I am, Sirs, yours faithfully,

Nov. 25th, 1898. W. WOODWARD, M.D. St. And.

*** The best advice we can give our correspondent is that he should procure, or consult, a copy of the Local Government Board's report on "Oyster Culture in relation to Disease" (Eyre and Spottiswoode). He will there find a detailed description of practically all the oyster layings in England.—ED. L.

THE QUALIFICATION OF L.A.H. DUBLIN.

To the Editors of THE LANCET.

SIRS,—Will you kindly inform me through your columns whether the L.A.H. Dub., 1880, is a double qualification, and if the holder of it is legally qualified to hold Government, municipal, or surgical appointments?

I am, Sirs, yours faithfully,

PUZZLED.

Nov. 19th, 1898.

*** The Licence of the Apothecaries' Hall of Dublin in 1880 was, as it is now, a licence in *medicine* only.—ED. L.

THE TALE OF A THREEPENNY-BIT.

HIS Honour Judge Edge, recently translated from a county-court district in Devonshire to Clerkenwell, enjoys, we believe, a high reputation in the legal profession for knowledge of all things essential to his position. Among these seems to be included an acquaintance with the relations existing between the hospitals and the public. Having before him not long ago a defendant who though reported to be well off had recently been an inmate of a hospital and who gave this as an excuse for his inability to pay his creditor, the learned county-court judge asked him searching questions as to a donation which he had made to the hospital funds. He also told an anecdote of a

Digitized by Google

gentleman in evening dress who after being attended to in a hospital, presumably for an accident, asked for the donation-box and ostentatiously put money into it, the end of the story being that on the box being opened the coin deposited in it turned out to be a threepenny-bit. The defendant before Judge Edge seems to have found himself neatly placed between the horns of a dilemma. If he named a large sum he proclaimed his means and if he named an infinitesimally small one he convicted himself of hypocrisy, for obviously no one is expected to requite a hospital for what it may do for him in a case of urgent need unless he can afford to give something more than, say, 6*d.* or 1*s.* That the defendant in question had not hit upon any suitable sum between the two extremes suggested is a fair inference from the fact that he did not state the amount he had in fact contributed, and the sum by which the hospital was benefited remains a matter of pure speculation. Leaving his case, however, out of the question his Honour Judge Edge showed by his remark "I really consider that the way our hospitals are abused by persons well able to pay is a gross scandal" that a county-court judge as well as a hospital secretary may recognise a frequent association between means and meanness that goes beyond a mere similarity of sound.

LECTURES TO NURSES.

To the Editors of THE LANCET.

SIRS,—It may interest your readers to know the questions which were recently set at an examination for ladies in "First Aid" at the Polytechnic. Very little was said during the five lectures on anatomy and physiology, but at the examination (written), duration two hours, the following were asked:—1. Describe the alimentary canal. 2. Enumerate the bones of the cranium and describe the brain. 3. Describe the lungs and the pulmonary circulation. 4. Describe a muscle. To what injuries is it liable? 5. What is shock? The lectures were said to have been practical and interesting and dealing with first aid, but they did not prepare candidates for such a sweeping examination. There is an element of absurdity in the examination which should amuse the profession. I am, Sirs, yours faithfully,

Nov. 21st, 1898. A. B. C.

A FOOT ROLLER.

WE have received from Mr. Alfred Bentzen of Westminster-road, Birmingham, an appliance for which a claim is made that it tends to prevent corns and chilblains and to relieve tenderness and some other painful conditions of the feet. It consists of a roller about 4½ in. long and 1¼ in. in diameter, thickly covered with felt and mounted on two very short supports on which it revolves freely. The felt having been saturated with an oily solution supplied by the maker the roller is placed on the floor and the foot is passed to and fro over it. This is no doubt a stimulating exercise for the plantar structures and will help to counteract the ill effects of wearing tight boots. It might perhaps be of use in certain conditions of cramp or liability to cramp in the legs.

"WANTED A HOME."

To the Editors of THE LANCET.

SIRS,—With reference to the letter of "G. H." in THE LANCET of Nov. 26th I think he can find an asylum to undertake the charge of his patient for the sum he mentions—viz., £50 per annum. Peckham House Asylum, Peckham, would, I believe, do so, and I think there are others. He would, of course, have to be under certificate.

I am, Sirs, yours faithfully,

M. O. WALSHE.

Male Nurses' (Temperance) Co-operation, Thayer-street, Manchester-square, W., Nov. 28th, 1898.

"ENDERMIC MEDICATION."

To the Editors of THE LANCET.

SIRS,—Permit me, for the information of your correspondent "Vienna" in THE LANCET of Nov. 26th, to say that I have for the past two years successfully carried on endermic medication at the address given below and that patients sent to me by consultants or general practitioners are treated in accordance with their own wishes under my personal supervision and that the institution is open to them from 10 A.M. to 6 P.M., when their respective patients can be seen and examined by them, such remaining always the patients of those practitioners who send them. The institution is being fed by the most eminent in the profession.

I am, Sirs, yours faithfully,

E. KING HOUCHIN.

8, Osborne-mansions, Northumberland-street, W., Nov. 28th, 1898.

"THE TITLE OF DR."

To the Editors of THE LANCET.

SIRS,—I beg to draw your notice to the list of successful candidates for the Royal Naval Medical Service, indicating, as it does, that non-university men when placed in competition with university graduates show a high standard of proficiency in medical science. For it will be seen that the first four successful candidates are diplomates. The natural inference is that it is a gross hardship that the latter should be excluded from competing for certain appointments in civil life, as seen by the various advertisements where graduates alone are eligible. It also seems harsh at the present day that these diplomates should be prohibited by the authorities and discountenanced by a certain class of graduates from using the title of "Dr.," by which designation members of the medical profession are known to the public as such and which title is conceded to diplomates by public custom. Hoping you will find space to insert this communication in your valuable journal. I am, Sirs, yours faithfully.

Nov. 26th, 1898. FREDERICK W. COLLINGWOOD.

*** With those affected by the injustice which is meted out to diplomates under existing conditions we have every sympathy which we have expressed many times in our columns. For the London student better times are at hand we confidently believe. But in the meantime we cannot approve of the usurpation by diplomates of an incorrect style.—ED. L.

"TREATMENT OF VARICOSE ULCER."

To the Editors of THE LANCET.

SIRS,—In reference to the inquiry of "Ulcer" in THE LANCET of Nov. 26th under the above heading I should like to ask whether he tried a lotion composed of 80 gr. of nitrate of silver (crystals) and distilled water to 8 oz. One or two layers of fine butter-cloth should be saturated with this lotion and placed over the ulcer, a bandage of butter-cloth should be applied over them, and then a Martin's rubber bandage should be put over all. This lotion should be applied once daily and the bandaging should be most carefully done. The irritation (in my own cases) subsides and after a few weeks complete healing takes place. I am, Sirs, yours faithfully,

ARTHUR H. W. AYLING.

Wellington, Shropshire, Nov. 28th, 1898.

To the Editors of THE LANCET.

SIRS,—In reply to the inquiry in THE LANCET of Nov. 26th signed "Ulcer" I have found that some cases of varicose ulcers which did not yield to careful bandaging or even complete rest in the horizontal position were quickly cured when this treatment was combined with the internal administration of iodide of potassium. Seven-grain doses three times daily have sufficed, and I have usually combined with it three minims of liquor arsenicalis with compound infusion of gentian to one ounce. These cases showed no signs of syphilis, still, of course, the taint may have been there.

I am, Sirs, yours faithfully,

F. TAYLOR SIMSON.

Northumberland-avenue, W.C., Nov. 29th, 1898.

D.P.H. (Yorkshire).—We should say no. Our correspondent will find the question fully dealt with on pages 24 and 25 of the current Medical Directory. To answer quite definitely we should require a little more information.

Pro Bono Publico.—We do not publish anonymous letters however inclusive their dedication for good.

M.O.H. (open-air treatment of consumption) has omitted to enclose his name and address.

Query.—Yes, he is correct in so styling himself.

Z.—Under ordinary circumstances, no.

The Bradshaw Lecture

ON

THE UNION OF WOUNDS.

Delivered before the Royal College of Surgeons of England on Dec. 7th, 1898,

BY THOMAS PICKERING PICK, F.R.C.S. ENG.,

VICE-PRESIDENT; CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL; SENIOR SURGEON, VICTORIA HOSPITAL FOR CHILDREN.

MR. PRESIDENT AND GENTLEMEN,—It appears to me that there is considerable difference of opinion amongst surgeons and pathologists as to the way in which simple wounds unite, especially as to whether the process of healing is an inflammatory one or not. In selecting a subject for the Bradshaw Lecture this year I thought that I could not do better than discuss this question and see whether by a consideration of the subject we can arrive at some distinct conclusion. I have formed a very definite opinion myself and it remains to be seen whether I shall succeed in winning you round to the same view that I hold.

REPAIR WITH OR WITHOUT INFLAMMATION.

Many surgeons and pathologists, and amongst them some of the most eminent in this country and on the Continent, believe that the union of wounds takes place without inflammation and, indeed, assert that "repair in all its forms is effected without inflammation." These pathologists teach that "repair and inflammation are not only not identical but that they are incompatible; that repair is a constructive physiological process and resembles closely that of development and growth, but that inflammation is a destructive pathological process brought about entirely by micro-organisms introduced from without; and that when it attacks a wound in the process of repair it at first checks repair and later brings about disorganising changes; and when a part repairs after it has been the seat of inflammation it does so only when the inflammatory process has been arrested."[1] Other pathologists, again, hold the opinion that all wounds unite by a process which they regard as inflammation. And while admitting that inflammation is a destructive pathological process they believe nevertheless that the union of wounds takes place by it, and that there is a decrease in the vital activity of the affected tissues, and, as a result, a lower vitality in the product of this inflammatory process—I mean in the scar or connecting medium which binds the severed parts together. There can, I think, be little doubt that John Hunter believed that wounds may heal without inflammation. In fact, in one place he distinctly states in his lectures "that primary healing takes its course without inflammation and is painless." He did not, however, greatly emphasise the fact and appears to have believed that the bond of union in these cases was extravasated blood. He thus describes the process: "The blood"—that is, the blood extravasated into the wound—"being alive, this uniting medium becomes immediately a part of ourselves and the parts not being offended by it no irritation is produced. The red particles are absorbed and nothing but the coagulating lymph is retained, which, being the true living bond of union, afterwards becomes vascular." But John Hunter certainly did not believe that "repair in all its forms is effected without inflammation," for he states that "in many diseases it is the first step towards a cure." I do not propose, however, to weary you further with the opinion of the older pathologists; I prefer rather to limit myself to a consideration of the question as it exists at the present time as to whether wounds heal without inflammation; and I take as my text on which to base our discussion the words of Karl Roser of Marburg, a German pathologist of great repute. He says: "The clean, non-infected wound heals without inflammation by first intention; the infected wound, on the contrary, heals by second intention with the appearances of inflammation. In the first case healing follows immediately after the injury. In the other case inflammation intervenes between injury and healing as a disturbing complication."

Clearly the first point in considering this question is to have a clear and definite understanding of what inflammation is. As you are all aware, Dr. Burdon Sanderson has defined inflammation as the "succession of changes which occurs in a living tissue when it is injured, provided that the injury is not of such a degree as at once to destroy its structure and vitality." Or, more briefly and succinctly, that inflammation is the "response of living tissues to injury." Now, if we accept this definition the whole question falls to the ground at once. Clearly, if this is true, no wound can unite without inflammation—a wound is an injury; therefore, a response must take place, a succession of changes must occur which constitutes inflammation. Those, however, who believe that wounds heal by a strictly physiological and constructive process clearly do not accept this definition of the word and regard inflammation as something else. The older definition of inflammation was that it was that condition which was attended by certain so-called cardinal signs—pain, heat, redness, and swelling—and that we must regard these signs, to again quote the words of Dr. Burdon Sanderson, "as the characteristics of the thing of which the word 'inflammation' is the name." There is no question that these signs do attend or follow a wound, and so again we must admit that if the aggregate of these signs constitutes inflammation, then that there is inflammation during the process of healing of a wound.

The opponents of the theory that wounds heal by inflammation admit that the four cardinal signs of inflammation are present, but they do not admit that therefore there is inflammation. Let me quote to you what Mr. Bryant says in his "Practice of Surgery" on this point. Speaking of wounds he says: "Within an hour or an hour and a half the edges of the wound will be seen to be swollen and slightly red from increased vascularity, and if the connective tissue of the wounded part is loose, as in the eyelids or male genital organs, it will be puffed up and œdematous. To the patient the part will feel hot and stiff and it will be the seat of a dull, aching, or burning pain. The edges of the wound will also probably be more sensitive, the amount of pain depending much upon the tension of the parts and upon the treatment to which they have been subjected. If the edges of the wound have been stitched together and the parts are much swollen and œdematous there will be tension upon the wound and a disposition to separate and gape. In a healthy subject, however, where repair goes on well, all these local phenomena will subside and disappear in the course of two, three, or four days, according to the rapidity and perfection of the healing process, and a cure will then take place. But should the local phenomena above described be more persistent, increase in severity, spread beyond the margins of the wound and surrounding parts, or alter in character for the worse, what has been a physiological reparative process will pass into a pathological or diseased one and the parts will then be said to be inflamed." The opponents of the doctrine of the healing of wounds by inflammation do not therefore hold that the presence of these four signs necessarily constitute inflammation; and no doubt this, in fact, is quite true. They are present in that condition which indeed is the first stage of the inflammatory state, but which may also occur quite independently of it—a condition to which we apply the term "determination," and which is undoubtedly a physiological process and is an element in thousands of actions of daily life and occurs in those conditions where a sudden increase of blood is required for some physiological purpose. Thus, a morsel of food is introduced into the mouth requiring an increased quantity of saliva for its salivation; immediately a determination of blood to the salivary glands takes place, causing a more active secretion and an increased flow of saliva.

The first use of the word "determination" has been attributed to Paré. John Hunter called it the "incipient enlargement of the vessels," and in no part of his treatise on Inflammation does he use the word "determination." He says: "The very first act of the vessels when the stimulus which excites inflammation is applied is, I believe, exactly similar to a blush. It is, I believe, simply an increase of distension beyond their natural size. This effect we see takes place upon many occasions—gentle friction of the skin produces it—gentle stimulating medicines have the same effect." As a German equivalent to the word "determination" Virchow introduced the term "Wallung" (surging) which has been constantly used by his successors. This determination, which we admit is a physiological process, is attended with a sudden afflux of blood to a part and is characterised in consequence

[1] ant: Hunterian Oration, 1893.

Digitized by Google

by certainly, at least, three of the four cardinal signs of inflammation—heat, redness, and swelling, and possibly also in many cases by the fourth also; for, at all events, if there is not actual pain there is an uneasy or abnormal sensation, such as a sensation of fulness about the part. It is evident, therefore, that we are not in a position to say that a part is inflamed because of the presence of these four symptoms. I have alluded somewhat at length to this question of determination because I think it is important, with a view to accuracy of statement, that the employment of the word "determination" should be strictly limited when used in connexion with the inflammatory process to the primary acceleration of the blood-stream in and about an injured part and should not be so extended as to comprise the subsequent stages of retardation resulting in stasis and exudation.

WHAT IS INFLAMMATION?

We have not yet arrived at our definition of inflammation; and, indeed, the difficulty is great in giving a clear and logical definition to this form of disease, although we easily recognise the condition and understand the combination of processes which are taking place in the tissues. I should regard inflammation as a modification of the normal physiological processes in the various tissues of the body resulting from the application of some irritant to the part, this process being attended or followed in most cases by the formation of a new material of a less highly organised nature than the original tissue in which the inflammation has taken place. And here I would draw your attention to a very important point, and one which it is very desirable that we should keep strictly in our minds, and that is, that these cases of what we may call "traumatic inflammation"—that is to say, inflammation produced by a wound in which no foreign body is allowed to remain—and which inflammation is, as I hold, necessary for the healing of the wound, are very different from those inflammatory processes which are due to the admission of septic organisms. And they differ especially in this marked peculiarity—that the irritation in the tissue does not extend beyond the immediate neighbourhood of the injury. The irritant which has produced the inflammation has been momentarily applied and therefore the inflammation which results has a tendency speedily to resolve itself as soon as it has brought about those changes which are necessary for repair. This is very different from those cases where a prolonged irritant is applied to a part, then the process of inflammation is also prolonged, and when this irritant is some septic organism which has the power of multiplying in the tissues and of producing ptomaines which poison the tissues, the inflammation is not only prolonged, but has a tendency to spread and diffuse itself rapidly by continuity of tissue.

It must be admitted on all hands, I think, that in the process of union of wounds there is the formation of a new tissue which forms the bond of union and the point which we have to discuss is whether this new tissue is the result of inflammation or whether it is merely a physiological process, a condition of ordinary development or growth which is constantly taking place in the body. If we regard the subject from a clinical aspect I admit that there is considerable difficulty in making any distinction between these two conditions; for, as I have endeavoured to show, we may have all, or almost all, the signs of inflammation as the direct outcome of a physiological process and, on the other hand, we often meet with cases of wounds which heal without any of the four cardinal signs being present in any marked degree at the margins of the wound, though I believe they are always present to a certain extent, though it may be this extent is not appreciable to the ordinary observation. And it must be borne in mind that the difference between slight redness, swelling, and heat of the edges of a wound and the most intense form of these conditions is only one of degree, the latter being patent at the merest glance to the most superficial observer, whilst the former is so slight as to be scarcely distinguishable to the most careful investigator. When, however, we come to consider the question from an histological standpoint it seems to me that we cannot separate it from an inflammatory process however slight its extent and intensity may occasionally be. Let us then examine the subject from an histological point of view and et us first consider the manner in which adhesion of the edges of a wound takes place, whether this process is regarded as inflammatory or not, and this we will do in the briefest possible manner by simply stating the most salient points which have been observed so that we may clearly carry them in our minds. And in order to do this we will take an example of the simplest kind of tissue in which an incision has been made and which unites by what is called adhesive union or the "first intention" of John Hunter. For I do not propose at present to say anything about the so-called "immediate union of wounds," which was first described by Macartney, as I do not believe that such a condition exists. I shall have something to say, however, about this at a later period of my lecture.

THE PROCESS OF HEALING.

Suppose, then, we make an incision through the skin into the subcutaneous tissue beneath. What happens? First it bleeds, then the bleeding ceases, and finally union takes place. The wound first bleeds because the capillaries contained in the tissue are divided; the bleeding stops because the blood coagulates in the capillaries as far as the nearest anastomosis—that is to say, to the next point of intersection of the capillary network. So that the first change is that all the cut vessels become filled with clots up to their first collateral branch, and this is undoubtedly simply a physiological process, the clotting being the result of the physiological conditions which bring about the formation of fibrin. Secondly, the capillary vessels in the neighbourhood, that is to say, beyond the point of clotting, will be noticed to be dilated. By some this would also be regarded as a physiological process and to merely arise from mechanical causes, from the increase of pressure to which the capillaries have been subjected in consequence of the coagulation which has taken place in their several extremities. About this I shall have to say a word or two in a moment; but let me first glance at the other changes which are to be observed in a wound before the process of union is effected. The third change to be noted is in the connective tissue in which the vessels ramify. This becomes infiltrated with cells and these cells multiply, so that we have the tissues at the edges of the wound infiltrated with a vast accumulation of cells which are for the most part simple nucleated cells resembling leucocytes. After a time other larger cells appear and some of these find their way to the surface of the wound and are to be seen covering it. Fourthly, the cells which cover the surface of the wound undergo a developmental process and first becoming spindle-shaped and then fibre-cells are eventually converted into fibrous or scar-tissue which forms the cicatrix or bond of union. Finally and lastly, the capillary network at the margins of the wound prolongs itself in the form of loops into this new tissue and becomes continuous with similar loops on the opposite side and thus the new tissue becomes an organised structure and unites the edges of the wound together. These, very briefly, are the changes which can be observed with the microscope as taking place in the edges of a wound whereby union is effected, and the question we have to consider is whether these changes are strictly physiological and akin to those of development or growth or whether they are the result of that pathological process which we know as inflammation—whether, in fact, these cells which are the essential elements in the process of union find their way between the edges of the wound in conformity with known physiological laws and, having found their way there, undergo changes similar to those which are witnessed in the embryo, when the blastodermic cells of the ovum grow, develop, and differentiate into the various structures of the human being; or whether these changes take place as the result of a pathological process altogether different and distinguishable from normal physiological action. In discussing this point we shall have to consider four questions:—1. Is the dilatation of the blood-vessels, which we described as the second change in our process of union, simply a mechanical one and due to the increased pressure exerted on the capillaries of the part? 2. Is this vast accumulation of cells in and around the wound the simple outcome of a physiological process? 3. Are the changes which take place in the cells exactly identical with the mode of growth and development in embryonic cells? 4. And, lastly, What is the nature of the newly-formed tissue?

The first point, then, which we have to consider is whether the dilatation of the blood-vessels, which undoubtedly occurs, is simply due to mechanical causes. We have seen that when a wound is made the blood-vessels at its margins become blocked, and it is perfectly clear that the blood will have to accommodate itself to this and find another channel by the existing and patent by-paths around the blocked vessels.

Digitized by Google

The result of this is increased pressure in these parts and as a consequence distension and dilatation of the vessels. So there can be no question that in this simple mechanical explanation there is a way in which we may account for the dilatation of the blood-vessels, but unfortunately this mechanical explanation does not fully account for the subsequent changes which take place. It fully explains the first step in the process—the determination with increased motion—but it does not explain the determination with diminished motion in which the circulation becomes slower and slower until the retardation results in stasis, with consequent diapedesis. For this we must look to some other cause than a mechanical one, and hence, as it is certain that this slowing of the blood current does take place, we cannot accept the theory that the dilatation of the blood-vessels in inflammation is entirely due to a simple mechanical cause. To what then must we attribute this dilatation and this increased flow of blood? Numerous hypotheses have been advanced at different times as to the cause and it cannot be said that even at the present time any one of these hypotheses gives a really complete and absolute explanation of the phenomenon. In considering the question I would strongly emphasise and ask you to bear in mind the words of Sir John Simon who says that "a part does not inflame because it receives more blood; it receives more blood because it is inflamed." For if we do not admit this the whole argument falls to the ground. It is self-evident that the proximate cause of the dilatation must be change in the tonicity of the muscular coat of the vessels and the question we have to determine is how this change of tonicity is brought about. It at once suggests itself that this may be due to some irritation which disturbs the function of the nerves of the vessels. And this may to a certain extent be so, especially as it has been proved by direct experiment that irritation of a sensory nerve causes dilatation of the arteries in the whole area to which the nerve is distributed. Why this irritation of a nerve should produce this active, directly paralysing effect is not quite so clear, though I think it may be very fairly explained in the following way. We know that the vagus nerve possesses an inhibitory action upon the heart and that irritation of this nerve produces a diminution or obstruction in the action of this organ. We therefore assume that there is an inhibitory nervous system which arrests the contraction of muscles. And if this is true of the heart, why should it not also be true of the blood-vessels? and why should we not assume that the muscular elements of the blood-vessels, like the heart, are under the control of both the sympathetic and the cerebro-spinal system, the former of which causes the rhythmical contraction of the vessels, and the latter regulates and obstructs their contraction? If this is so it would explain the reason why irritation of the cerebro-spinal nerves would exert an inhibitory effect upon the muscular coat of the vessel and as a consequence vascular dilatation. But it is quite clear that this explanation of the cause of dilatation of the blood-vessel is not sufficient to explain the phenomenon. It is true that part of the dilatation may be due to this cause, but I am inclined to think it is only a very small part; for it is clear that if this was the cause, and the sole cause, the dilatation would not be confined to the injured area, but would embrace all those parts supplied by the nerve irritated. Moreover, experiment and clinical experience negative this view. The experiments are those of Cohnheim, who has shown that in the tongue of a frog after its nerves have been severed the process of inflammation can be excited by almost any irritant, and, indeed, that where the tongue has been severed from all its connexions, so long as the arteries and veins are allowed to remain intact an inflammation can be excited by similar causes. It is certain here that the dilatation is not dependent on any influence conveyed to the blood-vessels from the cerebro-spinal centre. Clinical experience also points in the same direction. I need only allude, in illustration, to the fact that it is a matter of every-day experience to see inflammation set up in paralysed parts, where the nerves clearly can have nothing to do with the primary condition of dilatation. We must look, therefore, to another cause to explain the dilatation which takes place in the inflamed area. I think it may be briefly stated to be due to the direct effect produced upon the vessels of the part by the injury which has caused the disturbance, or, in other words, that the irritation disturbs directly the function of the muscular coat of the arteries and veins and the living cell substance of the capillary walls. This is in strict accord with Cohnheim's so-called "alteration" theory of inflammation—namely, that the "alteration of the physiological condition of the walls of the vessels is the cause of those phenomena and processes the sum of which is designated by the term inflammation." The experiment on which Cohnheim based this proposition was by cutting off the circulation from a part for a certain length of time, say, twenty-four hours, by encircling it with a ligature, and then at the expiration of this time loosening the ligature and restoring the circulation. By this means he produced as typical and intense an inflammation as by subjecting the part to the direct action of an irritant. By thus depriving a part of blood he unquestionably altered the physiological conditions of the blood-vessels and other tissues and this changed or abnormal condition was the proximate cause of the dilatation of the blood-vessels as well as the other phenomena of the inflammation. If, then, this undoubted alteration in the walls of the blood-vessels—the part with which the blood first comes into contact in these experiments—causes them to act as if they were inflamed, may we not assume that a similar change takes place in the vessels when inflammation is set up by other causes and induces a similar result? If we accept this as true we have a strong argument in support of the view that inflammation is necessary for the repair of tissue and therefore for the union of wounds. For we have here in the vessels a deterioration of tissue, a retrograde metamorphosis, which certainly cannot be regarded as a healthy physiological action; a something which is quite different from the *afflluxus sanguinis*, the active congestion or determination of blood which is due entirely to nerve influence.

We pass on now to consider the second question which I set myself—namely, Is the vast accumulation of cells in and around a wound during the process of healing the simple outcome of a physiological process? In order to answer this question we have to ask ourselves another: Whence do they come? I suppose there is no one here present who would hesitate in answering that, at all events to a very considerable extent, they are emigrated leucocytes. And this is undoubtedly one source from which they are derived, though I think there is very little doubt that they are also in part derived from a second source. Into this point, however, it is foreign to my purpose at present to enter; and it is sufficient that we believe that the myriads of round cells which we see in and around a wound during the early stage of the healing process were originally derived in part from the leucocytes which have passed out of the circulation through the walls of the capillaries. We then ask ourselves another question, Why has this emigration taken place? It is a condition very different from what we observe in health. For though it cannot be denied that exudation of the plasma of the blood takes place as a physiological process and emigration of the leucocytes very probably does so, still it is a very different condition to what we see in a wounded part and we never find in healthy tissues the whole of the structure infiltrated with leucocytes to such an extent as almost, if not quite, to obscure the natural structure of the part. There is no doubt that the answer to this second question is that the emigration is due to stasis or that condition of arrested circulation which we know speedily follows the dilatation of the blood-vessels in an inflamed part. And then we ask ourselves a third and final question, What is the cause of this stasis?

Many theories have at different times been put forward to explain this phenomenon. It has been attributed to the dilatation of the blood-vessels, to changes in the corpuscles, and to changes in the tissues, especially the lining membrane of the walls of the vessels. It cannot be due to the dilatation of the walls of the vessels because we do not find a similar phenomenon attending the dilatation of vessels from other causes. Division of the sympathetic in the neck of an animal causes dilatation of all the vessels of the head and face from paralysis of the muscular coat of the blood-vessels, but there is no tendency to stasis or arrest of the circulation. Then, again, it cannot be due to changes in the corpuscles, for if we examine the mesentery of a frog under the microscope in which inflammation is slowly set up from exposure to air we may watch a leucocyte showing a tendency to stick to the wall of the vessel so long as it is contained in the inflamed area; it partially adheres, oscillates to and fro, but gradually makes progress onwards till it reaches the extreme limit of the inflamed area, when it at once loses this tendency to adhere and flows on rapidly in the normal course of the circulation. Another reason why it cannot be due to changes in the corpuscles is because if it were we must assume that not only

Digitized by Google

the corpuscles in the inflamed area are changed but all the corpuscles throughout the body, and therefore this same adhesiveness must be observable in every vessel in the body, for only one small portion of the blood was acted upon by the irritant which set up the inflammation, and the blood in the area of stasis cannot be that which was thus acted upon. Stasis must therefore be due to changes in the walls of the vessels or the tissue with which the blood comes in contact, so that the corpuscles when they pass into the injured area acquire a tendency to adhere. The lining membrane of healthy vessels differs from every other solid in the fact that the corpuscles have no tendency to adhere to them and therefore no coagulation of the blood takes place; but when the corpuscles, and especially the leucocytes, come in contact with any foreign body—that is to say, anything else except the healthy wall of the vessel—they show an immediate tendency to adhere to it, to disintegrate and set free their fibrin ferment, and coagulation is the natural result. The same thing holds good if the lining membrane becomes altered in structure or diseased. It no longer possesses the power of repelling the corpuscles but on the other hand attracts them and causes them to adhere. It acts as a foreign body. Look, for example, at many cases of thrombosis where the coagulation is due to an altered state of the vessel wall which causes the leucocytes to adhere to it and as a consequence the vessel becomes occluded with clot. Or, again, look at the natural process of cure in an aneurysm. The lining membrane of the sac is an altered tissue from the ordinary lining membrane of an artery; it is a foreign body—a something other than the wall of a healthy vessel. In consequence of this the leucocytes adhere to it; they disintegrate, they set free their fibrin ferment, and thus fibrin, the active clot of Broca, is formed on the interior of the sac. In the fact then that in the union of wounds we have the tissues in and around the wound infiltrated with cells we have another strong argument in favour of the theory that the union of wounds is an inflammatory process. This infiltration with cells is the direct outcome of stasis in the vessels and this stasis is a necessary result of their deterioration or retrograde metamorphosis which can scarcely be regarded as a physiological process.

In connexion with the third question which we set ourselves to consider, whether the changes which take place in the cells, which are now believed to be in a great measure large mobile cells formed by proliferation of the original cells of the part which have replaced the emigrated leucocytes, are exactly identical in their mode of growth and development with embryonic cells, I am bound to say that I know no difference. It seems to me that we must acknowledge that these cells of granulation tissue are exactly identical with embryonic cells and behave in the same manner, undergoing the same form of development into higher tissues. It would appear that the recognition of this fact has caused objections to be raised against designating as inflammatory the purely regenerative processes which take place in the healing of a wound. But I would contend that it in no wise invalidates my argument that the new formation of tissue which leads to the adhesion of wounds is inflammatory. My contention is that this newly formed tissue, which is by a process of development eventually to form scar tissue, or the bond of union between the severed tissues, is the result of an inflammatory process, though the subsequent steps by which it undergoes development into scar tissue may be distinctly physiological, or at all events identical with processes which take place in the blastodermic membrane of the embryo where the primary nucleated masses of protoplasm of which it is composed undergo changes of growth, multiplication, and differentiation until they become converted into complete animal cells of many different types. It is the mode of origin of the cells and not their subsequent changes which marks off the process of union of wounds as an inflammatory one.

INFLAMMATION ALWAYS PRESENT.

Leaving this point we pass on to consider the fourth and last question which I stated it was my intention to bring under your notice in elucidating the point which we have under consideration. The question is as follows: What is the nature of the newly-formed tissue which acts as a bond of union and joins the two severed surfaces together? And in the answer to this question I think we shall find one of the strongest arguments in favour of the view for which I am contending—namely, that wounds always unite by a pathological process which we term inflammation.

The elucidation of this point will require a little careful consideration. So long as tissue elements retain their vitality they possess the power of undergoing nutritive and formative changes on the application of a physical or chemical stimulus. Up to comparatively recent times the knowledge of this fact caused pathologists to regard inflammation as a condition of increased, though perhaps perverted, activity of the process of nutrition. The converse of this is, however, the fact. Lord Lister was the first to initiate the doctrine that "inflammation consists not in increased but in diminished vitality of the tissues affected." The process of inflammation, whether showing itself by enlargement, multiplication, or formation of cells, is always a sign of lower vitality and results, as Dr. Burdon Sanderson expresses it, in "tissue spoiling and not in tissue stimulation." And the more rapid the rate of reproduction the less is the stability of the newly-formed tissue, and those tissues which are the result of the inflammatory process are always more lowly organised and of a lower vitality than the original tissue of the part before the process of inflammation took place. Inflammation must be regarded therefore as a destructive process. If we admit this—and who will gainsay it?—we have an extremely strong and potent argument in favour of the fact that the scar tissue or bond of union in a wound is a product of inflammation and not a new formation the result of a physiological process.

Let us briefly consider what scar tissue is. It is composed of dense white fibrous tissue which differs from the normal tissue which it has replaced in many important particulars. And as Rindfleisch says, "Cicatricial tissue is far from being a connective tissue of ideally high quality." It is more dense than ordinary areolar tissue and contains no yellow elastic fibres. It is smooth on the surface and presents no papillæ. It is devoid of sweat glands, sebaceous glands, or hair follicles. It contains no lymph spaces or lymphatics and nerve fibres are very few in number or altogether wanting. When first formed it is vascular, but its vessels soon disappear and it becomes dry, hard, and white and of lower organisation than the natural parts. Moreover, scar tissue is exceedingly prone to diseases of degeneration. How common a thing it is to find a scar breaking down and ulcerating and how slow these ulcers are to heal and how liable to recur. And, again, how frequently we find scar tissue becoming the seat of epithelioma, constituting what was first described by Mr. Cæsar Hawkins as the "warty tumour of cicatrices." And even keloid must be regarded as a disease of degeneration, for though there is an excess of growth this growth consists of a lowly organised fibrous tissue, intermingled with cells, which are arrested in their progress of development, and degenerate in their incomplete forms. If, then, this is the character of scar tissue it can scarcely be regarded as the product of a healthy physiological process and it becomes a powerful argument of the view that union of wounds is an inflammatory and therefore a pathological process and not a physiological one.

This, then, is the evidence which I have to bring forward in favour of the view I am upholding and it only remains now for me to endeavour to reconcile this view to the doctrine of the different forms of union of wounds.

In our text-books on surgery it is customary to describe five classical ways in which wounds unite: (1) by immediate union, primary adhesion, or direct growing together of the severed surfaces; (2) by first intention; (3) by scabbing; (4) by second intention; and (5) by secondary adhesion or growing of two granulating surfaces together. To these I think we ought to add another—namely, healing by blood-clot. It will be my endeavour to show that there are only two ways in which union of wounds takes place—namely, without suppuration and with suppuration; and, moreover, that the difference between these two conditions is very slight, being one more of degree than of kind, and that they are both the result of the same morbid process going on in the part—that is, inflammation.

DETAILS OF MODES OF UNION.

Let us consider these different modes of union a little more in detail. It is the first of these that I most desire to consider because it is a mode of union in which the essential principle was laid down by Macartney, of Dublin, who first described it, that there was no inflammation. He says: "Union takes place without any intervening substance such as blood or lymph." We are told that when the surfaces of a clean-cut wound are carefully adapted and

Digitized by Google

supported they will probably be found to present no signs of inflammation appreciable to the senses and in the course of from twenty-four to forty-eight hours the wound will be so soundly united as to require no further attention, nothing being left except a linear mark which at first looks more or less red but gradually fades away and in the case of small cuts disappears altogether. This is hardly an intelligible account of what takes place. In what does the process of union consist? There must be some process by which the severed surfaces are caused to adhere together and to become united in such a way as to present no trace hereafter of where the union has taken place. And, again, what is the nature of this linear mark which at first looks red and then gradually fades away? And, finally, must we assume that there is no inflammation because there are no signs appreciable to the senses present? I confess that this theory of immediate union is beyond my comprehension and I have searched for an intelligible account of what takes place without being able to find it. Hear what another author says: "When wounds unite by immediate union no other changes than these"—namely, coagulation in the vessels up to the nearest anastomosis and dilatation of the capillaries in the neighbourhood—"take place beyond the gradual restoration of the capillary circulation through the parts that have been divided and under such somewhat rare circumstances no scar or cicatrix is left. The soft parts at first simply adhere together and subsequently become continuous." But why do they adhere? How do they become continuous? What becomes of the clots in the vessels and why do the neighbouring capillaries dilate? Another author says: "The divided blood-vessels and nerves are brought into perfect contact and reunion ensues by the opposed surfaces simply growing together." Very simple; but I confess that I should like to be told how they grow together. Does the author mean that when the parts are replaced that each minute filament of nerve and the open orifice of each capillary vessel is brought into "perfect contact" with its corresponding and severed half on the opposite side of the wound? The idea is of course absurd. It seems to me that we must acknowledge the presence of some connecting material which shall first cause the cut surfaces to stick together and through which they shall become continuous, just as much as in the case of two pieces of wood which we cannot make stick together without the intervention of some adhesive material.

I for one, therefore, must discard the doctrine of the first mode of union of wounds as untenable. I explain those cases in which it is said to occur—and I must confess that I have never been so fortunate as to observe the process in my own experience—as cases where the inflammatory process is reduced to a minimum and where, therefore, the adhesive material is correspondingly small. Direct experiment negatives the proposition. If a wound, however small and however carefully adapted immediately after its infliction, be made, it will be found upon killing the animal and making sections of the injured part that there is a greater or less amount of connecting substance between the edges of the wound. Even if a very small incision be made through the cornea of a rabbit with the sharpest knife and be prevented from gaping by at once closing the eye the resulting cicatrix will be invisible to the naked eye, but nevertheless the intermediary substance may be demonstrated on microscopic examination. It seems clear to me therefore that we must exclude this fancied method from our category of modes of union of wounds and arrive at the conclusion that where union takes place very rapidly and without the ordinary signs of inflammation being appreciable to the senses that the difference is merely due to degree and that the same changes take place here as in the so-called union by the first intention, though to a less extent. For who shall say how much hyperæmia, how much exudation, and what amount of new formation of tissue is necessary to agglutinate and unite the edges of a wound together?

We proceed, secondly, to allude to the second mode of union of wounds—viz., union by first intention or by, as I believe, adhesive inflammation. I shall not say more about this mode of union than to mention that this would correspond to my suggested first division, that is to say, union without suppuration. I have already discussed this process very fully and the changes which take place in the part up to the conditions of complete union and which changes are admitted by all whether they are believed to be due to an inflammatory process or not. We pass on therefore to union by scabbing. This I believe to be merely a modification of the process of union by first intention and not to be worthy of being placed in a distinct class by itself. When a wound heals by scabbing the separative material which is poured out undergoes similar changes to those which take place in the same material when the wound heals by first intention, the scab merely forming a protective film over the wound and preventing decomposition or putrefaction. Union by blood-clot is another mode of union which can only occur in an aseptic wound and has only recently been described. It is merely another modification of union by first intention or by adhesive inflammation when the edges of the wound are not in contact but are separated by blood-clot which acts as a mould or framework into which the leucocytes and the plasma cells, the result of the inflammatory process, penetrate and where identically the same changes go on as in those cases where the edges of the wound are in close contact and where there is nothing between them but inflammatory exudation. It is obvious that all these modes of union are merely modifications of one process and are identical as far as regards the changes which take place. They may therefore, I think, with propriety be classed together as modes of union of wounds without suppuration.

It remains for us now finally to consider the two other processes or modes of union of wounds—namely, union by second intention and union by secondary adhesion, or, as it is sometimes called, "third intention"—two modes of union which I would venture to class together in one group as cases of union with suppuration. With regard to this mode of union it will be seen, I think, that it is merely a modification of the mode of union we have already described; that in both the essential features are identical and that the difference in the two is one rather of degree than of kind. The difference in the two would appear to be due to some circumstance which produces a prolonged irritation and therefore the resulting inflammation is prolonged and the amount of inflammatory exudation is increased. If we examine the changes which take place in this mode of union we find that we have the same initial changes, the same blocking of the severed vessels, the same hyperæmia around and the subsequent stasis, and the same exudation of what Hunter termed "plastic lymph." But instead of this exudation being slight in amount and speedily ceasing it goes on and on until the surface of the wound becomes covered with a considerable layer too thick to be nourished by the vessels in the underlying tissues. From malnutrition, therefore, the cells in the superficial layers undergo degeneration and are converted into pus cells and thus suppuration takes place. At the same time the deeper layers become vascular and converted into granulations which undergo cicatrisation and so the wound is healed. There can be no question, I think, that the cause of the prolonged irritation is the presence of septic micro-organisms in the wound. Time will not permit me to describe the process in detail, but sufficient has been said for my purpose which is to point out the close analogy between the process of union by the first intention and union by second intention. In both there is inflammation; in both this is attended with exudation, though varying in amount; and in both this exuded material forms the bond of union. In union by secondary adhesion or "third" intention we have the same exudation of inflammatory material acting as the bond of union. We have inflammation, exudation, and the conversion of the exudation into granulations. If these granulations are now brought in contact they coalesce together, just in the same way as the exudation does in union by the first intention. The vessels grow through this coalesced material from side to side of the wound, the cells of which it is composed undergo developmental processes and are converted into scar tissue and the union is complete.

Such then, Mr. President and Gentlemen, are briefly my views with regard to this important question of inflammation in connexion with the union of wounds. The whole subject hinges on the one point of what we mean by inflammation. If we agree with Hueter and Kocher that no injury alone is competent to produce inflammation without the intervention of micro-organisms, then my whole argument falls to the ground. But if we believe, as I do believe, that inflammation may be induced without the concurrence of organisms—an inflammation, I admit, different from that excited by these bodies, for it neither tends to spread to contiguous parts beyond the area of injury nor to infect distant parts through

Digitized by Google

the blood stream or otherwise—then I say I have brought forward conclusive evidence to prove that the union of wounds is an inflammatory process. At least, if it is not, I know not what it is.

The Purvis Oration

ON

SOME PRACTICAL POINTS IN THE TREATMENT OF THE CHRONIC FORMS OF HEART DISEASE DUE TO RHEUMATISM.

Delivered before the West Kent Medico-Chirurgical Society on Dec. 2nd, 1898,

BY A. ERNEST SANSOM, M.D., F.R.C.P. LOND.,

PHYSICIAN TO THE LONDON HOSPITAL, ETC.

MR. PRESIDENT AND GENTLEMEN,—Permit me to offer you my heartfelt thanks for the honour you have done me by inviting me to deliver the Purvis Oration. The invitation was as gratefully accepted as it was unexpectedly received. I have listened to many communications at the various London medical societies. Many such essays had been produced with much labour and reflected the earnest purpose of the writers, but yet only a small percentage of them has contributed definitely to the history of medicine and often the interest evoked has been fitful and unsustained. And yet how highly one ought to esteem these often self-denying labours. In a few instances one such communication has marked an epoch in medicine; in cases more numerous the student of a certain subject has found in the old records data of priceless value inciting him to the prosecution of new research. The value of the routine work of this society and of every such society in our midst cannot be doubted. A different set of conditions, however, obtains when one who has lived and worked among his brethren is asked to search among the stores of his own experience and present the conclusions of his thoughts to willing hearers. If I may be forgiven I will take a parallel from the experiences of my childhood. The boy who came into the family circle with the announcement, "I have a story to tell," was not always well listened to, while, "Uncle, tell us a story," was the signal for the assembling of hearers and the arrangement of serried ranks of chairs. I am grateful that you have asked me to tell a story.

THE SCOPE OF THE ORATION.

I will now come close to my subject. I have thought that it might serve some useful purpose if I gave you my own views as to the treatment of heart disease. The term "heart disease," however, is too wide in its significance. I had to narrow it down. I considered that on the whole it would be best to avoid definitions and to assume the hypothetical case of a patient, male or female, under the age of thirty-five years, coming to consult us for an indisposition which we have found by physical and other means of diagnosis to be caused by some structural cardiac disease. The limit of age, thirty-five years, makes the probability strong (in the highest degree) that the disease is of rheumatic origin. I say this dogmatically in the first instance. The conditions of disease are such that after the age of thirty-five years the factors of heart diseases are multiform and rheumatism plays but a small part in the causation. The "coming to consult us" is intended to imply that the patient is able to walk about. The disease is, or seems to be, not acute, but chronic.

I must now, at the risk of being thought prolix, explain what I mean by the term "practical." It has been said again and again, and lamented over, that the progress of therapeutics has not been commensurate with the advances in biology and pathology. I demur to this conclusion. It is only in the nature of things that the rate of progress should be slower in the one case than in the other. It is essential to us as scientific men that we should know what is the matter before we apply the remedies. We are all aware of the great difficulties which there are in our understanding and duly estimating the intricate processes of disease, but it is incumbent upon us to do all that we can to penetrate the gloom and to realise as in a picture before us the conditions, static and dynamic, not only of the portion of the organism diseased but of the organism in its entirety. We are thankful for the light afforded us by all methods of physical investigation. It is our duty to obtain knowledge as precisely as possible. Any rapid guess-work savours of charlatanry. The meaning of the word "practical" shifts with the epoch. In the time of Paracelsus it might have been considered practical to assert that a fit of the gout was due to a subsidiary demoniac messenger hurriedly sent to the great toe from the arch demon—the Archæus—within the body. In my own time, when I was a dresser, it was considered practical to amputate a limb without any of the antiseptic precautions now in vogue and to dress the wounds on principles which certainly were not Listerian. Very shortly before my student days it was practical (and inevitable) to do all surgical operations without anæsthetics. In the cases of amputations for diseases of bones and joints before the epoch of anæsthetics one patient in every three died; in the early days of anæsthesia (1854 to 1857) one in five died. To what extent this mortality is further reduced nowadays surgeons know better than I do, but at any rate it is receding to an almost insignificant figure.

ENDOCARDITIS IN THE FŒTUS AND IN EARLY CHILDHOOD.

I have said enough to indicate that by practical points in the treatment of chronic disease of the heart I mean practical therapeutics based upon as clear a knowledge as we can obtain of the morbid conditions. I now return to a consideration of the patient hypothetically before us who has a disease of the heart of, as I have asserted, rheumatic origin. I have already assumed such patient to be under the age of thirty-five years. But what is the limit of youthfulness? I must answer that disease of the heart of rheumatic form may be manifested during the very earliest years and even in intra-uterine life. In proof of this I feel that it will be of interest if I draw attention to a case in which disease of the heart was discovered in the fœtus during life and verified after death. A healthy girl, aged seventeen years, was admitted into the Hospital of La Pitié, Paris, in January, 1880. She was in the last month of pregnancy and came to the hospital only for her accouchement. The case was most completely observed by Professor Peter who found the uterine signs quite normal and there were evidences of a fœtus endowed with much muscular activity. Auscultation demonstrated the sounds of the fœtal heart, but instead of these being of the usual regular "tic-tac" characters there existed a loud, harsh murmur followed by a short, sharp noise just like the normal second sound. The rate of the fœtal heart-beats was 130 per minute. Parturition occurred in a perfectly regular manner and a male infant was born—pale, apparently ex-sanguine, and in a moribund state. The death of the infant soon followed. At the post-mortem examination the heart was found to be enormously dilated and hypertrophied in the right chambers, while the left auricle and ventricle presented normal characters. The tricuspid valve showed all the signs of endocarditis, vegetative and sclerous. There were numerous vegetations on the free border, and the tendinous cords, thickened and shortened, caused such retraction of the firm fibrous curtains of the valve toward the ventricular wall that tricuspid insufficiency was manifested in the most marked degree. The reporter of the case considered that the hypertrophy of the right chambers of the heart must have been rapidly produced for it was evident that the endocarditis had developed subsequently to the closure of the fœtal openings between the right and left chambers of the heart.[1]

I have quoted this case first to draw the attention of those who are in general practice or in obstetric practice in case their experience may tell of corroborative cases; secondly, to show that endocarditis with subsequent changes in the heart muscle and heart cavities, morbid phenomena identical with those of heart disease of the rheumatic form, may occur in the fœtus whilst the mother may be quite healthy and show no sign of rheumatism whatever.

Another case has been communicated to me by my friend

[1] Constantin Paul: Traité des Maladies du Cœur, Paris, 1887, p. 743.

Digitized by Google

Dr. J. O. Tunstall of Sutton Coldfield. In an infant who died very shortly after birth all the valves were found to be thickened and presenting numerous vegetations near their free borders. The valves of the right side were more affected than those of the left. There was no history of rheumatic fever or tendency thereto on the part of the mother. Dr. Dreschfeld, writing in Professor Clifford Allbutt's "System of Medicine," says: "Fœtal endocarditis is by no means a rare affection." Dr. Rauchfuss of St. Petersburg concludes that where there is no congenital malformation of the heart the valvular apparatus of the left chambers in the case of endocarditis in the fœtus is as frequently affected as that of the right. According to my own observations endocarditis involving the tricuspid is more frequent in young children than in later life. I found vegetations on the tricuspid valves in six cases out of thirty-two post-mortem examinations in all forms of valvular disease in children. The involvement of the tricuspid in the ordinary rheumatic form of endocarditis is not so frequently demonstrated in cases of adults. The explanation given by Dr. Byrom Bramwell founded on his own personal observations is probably correct—that the tricuspid is involved in acute endocarditis more frequently than is generally supposed, but the disease often passes away without the manifestation of such fibrous thickenings and retraction of curtains, cords, and columns as are frequently observed in the case of the mitral valve and the mitral orifice.

In the cases of fœtal endocarditis we have to form our judgment as to the rheumatic nature of the heart disease from the evidence of morbid anatomy alone. According to my own observations the morbid changes in the valves and in the cords and columns, as well as the consecutive alterations in the walls of the heart, are identical with those known to be in direct association with rheumatism. In the period of early childhood the clinical associations with rheumatism are more manifest, though the articular inflammation may be very slight and in a very considerable number of cases no signs or symptoms of implication of the joints exist. But in childhood the whole heart is profoundly affected by the rheumatic process. I said in my "Lectures on Diseases of the Heart in Childhood," published in the *Medical Times and Gazette* nearly twenty years ago: "In the child heart disease may be the forerunner of an attack of acute rheumatism, may occur at any period of the manifestation of articular phenomena, may arise when these are scarcely appreciable, and may become evident at any period after the subsidence of rheumatism. ..... As with the joint symptoms so with the pyrexia, the relation with the development of heart disease is by no means intimate. Wunderlich remarks that pericarditis and endocarditis can run their course without any elevation of temperature. They sometimes occur without elevating the temperature even a tenth of a degree. The conclusions are identical with my own."[2] Subsequent experience has abundantly confirmed these observations. In childhood the whole heart—pericardium, myocardium, and endocardium—is involved in the morbid process. The late Dr. Sturges termed the affection *carditis*, to express in a word this involvement, and he added: "Strictly speaking, carditis—inflammation, that is to say, both exocardial and endocardial — is exclusively rheumatic."[3] When we come to consider the conditions of heart disease in adolescence and in adult life, in its earlier and later periods, the evidence of morbid anatomy is to show that the changes are more widely spread than would seem at first sight. I said in my Lettsomian Lectures delivered in 1883 that the structures in the neighbourhood of an inflamed valve in rheumatic endocarditis—the fibrous tissues and the interstices of the muscular fibrillæ—were found on microscopic examination to be infiltrated with inflammatory exudation cells. Dr. Sturges[4] gave convincing proofs of the widely-spread infiltration of the heart muscle and similar conclusions have been enforced by Dr. Byrom Bramwell and other observers. More recently in papers read before the Royal Medical and Chirurgical Society on June 28th, 1898, Dr. D. B. Lees and Dr. F. J. Poynton have drawn attention to acute dilatation of the heart in rheumatic fever and to rheumatic dilatation of the heart in the rheumatism and chorea of childhood. Dr. Lees concluded from precise observation that an acute dilatation of the heart was a common occurrence in a rheumatic attack even when arthritis and pyrexia were slight and when there was neither distinct pericarditis nor endocarditis. Or an acute dilatation of the heart might be superadded to pericarditis and endocarditis. In the rheumatic affections of children the enlargement of the heart was demonstrated in a large number of cases and this enlargement receded as improvement set in. The careful and precise observations of Dr. Lees and Dr. Poynton confirm my own conclusions. I wrote in *International Clinics*, vol i., in 1894: "I am convinced that the rapid increases of dulness over the heart in rheumatism are not at all due to pericardial inflammation and the effusion of fluid; the whole heart may become swollen and dilated—swollen with the products of inflammatory exudation, dilated because of the enfeeblement of the muscle of its right and left chambers. In some cases this condition of swollen heart disappears without any of the friction signs of pericarditis being manifested; in fact, the heart and its serous membranes may pass through changes like those occurring in a joint inflamed through rheumatism. These variations in the bulk of the heart may be observed in some cases to be considerable from day to day and there may be repeated enlargements at intervals of a few days just as there may be repeated swellings in the joints." It must be borne in mind, however, that the enlargements of the heart bear no relation in time or in degree to the articular symptoms.

THE PROS AND CONS OF DIGITALIS.

Let us, then, revert to our patient who presents himself to us after convalescence from an attack of rheumatism. We find that there is something wrong with the heart—either morbid enlargement without other signs or murmurs indicative of incompetence of the mitral or aortic valves. Let us realise as the first practical point that even though weeks and months may have elapsed since the obvious symptoms of rheumatism it is most probable that the rheumatic disease in and about the heart is not absolutely quiescent. Slowly and without betrayal by symptoms the changes go on in the endocardium and the fibrous structures of the valve and its neighbourhood. If things go well a mere thickening results, the valve curtains remaining competent; if adversely there is contraction of the firm and thick tissue, degenerative changes supervene, and the valve becomes incompetent. But this may not be all; there may be waves of retrogression alternating with improvement, successive storms of disease with enlargements and shrinkings of the heart.

The first practical point, therefore, I would urge in regard to treatment is that we should realise that the problem is not the simply statical one of restoring a lack of power in the heart muscle, but a dynamical one of overcoming the influences of various factors and varying phases of disease. Take, first, the medicinal treatment. There are signs of some cardiac failure; shall we prescribe digitalis in some form? Consider the *pros* and *cons*. Many of us have had most favourable experiences of the usefulness of the drug. Suppose that the patient who has come to us has given evidence of the difficulty of breathing of effort, of some pretibial pitting or more marked signs of œdema of the lower extremities have appeared, and possibly of basic œdema of the lungs. Digitalis is given in the form of tincture, infusion, or powder and after a few days, perhaps even though complete rest has not been enforced, there is vast improvement—the output from the kidneys has been increased, the diuresis has cleared away the dropsy, and after some days of further treatment the adverse symptoms vanish.

But the experience of a second case may be very different. Administration of the drug fairly in, say, increasing doses during five or six days is followed by no sign of amendment. Perhaps there is evidence of intolerance in vomiting, of diarrhœa, of signs of faintness, of irregularity of the rhythm of the heart; or that, without any such signs, the drug disagrees; it is simply inert. The pulse is not rendered slow, the tone of the artery does not improve, diuresis does not result, and the dropsy persists or increases. How are we to interpret the facts? I think they may be briefly elucidated thus. If there be no rheumatic febrile disturbance and if the heart tissues are not undergoing active inflammatory changes digitalis properly administered acts well. If there be waves of active inflammatory action, circumstances not always to be readily discovered, digitalis fails. Such has been my experience. In a paper

Digitized by Google

founded on precise investigation by Dr. Lauder Brunton and Dr. Theodore Cash the authors thus express themselves: "The administration of digitalis or of drugs which act like it to patients in a febrile condition is likely to have much less effect on the pulse than at the normal temperature, and if the temperature be very high they may have no effect at all while this persists. When the temperature begins to fall the pulse naturally becomes slower and this slowness is increased if digitalis has been given at the height of the fever. It is therefore evident that digitalis and its congeners if they are given at all when the temperature is high should be given with great care, for otherwise the medical man may be induced by the apparent inaction of the remedy to push its administration too far during the fever, with the consequence of producing too great depression of the pulse during defervescence." I would supplement this by expressing my own opinion that not only during periods of rheumatic pyrexia but also when the heart structures are actively infiltrated during rheumatism, though it may be in the apparently chronic stages, digitalis is often inert or harmful.

REST AND TOPICAL APPLICATIONS: BEWARE OF MUSCULAR EXERCISES.

If two—or perhaps three—days have passed without improvement the drug should be omitted and the patient advised to take perfect rest in bed. Of course the withholding of the digitalis should be earlier if signs of intolerance arise. Now comes the question of counter-irritations or topical applications to the præcordia. Small blisters may be applied after the manner recommended by Dr. Caton[5] of Liverpool—one of the size of half-a-crown near the heart's apex and when the consequent irritation is subsiding a second blister of similar size close to it, and others following. Or these small blisters may be placed over the intercostal spaces. In France the thermo-cautery (*pointes de feu*) is more frequently employed. Though these methods may tend to relieve subjective symptoms I have not been convinced that they have had any decided therapeutic effect. I think that there has been much more decided evidence of amendment from the topical application of the ice-bag as recommended in pericarditis by Dr. D. B. Lees. An ice-bag suspended from a cradle should rest lightly over the heart-region, a thin layer of flannel intervening. The ice-bag may be applied for periods of half an hour and removed for like periods. Usually the patient is made comfortable by these means and the heart-tumult is allayed. A temporary dilatation of the heart may under such treatment subside in two or three days. A small hypodermic injection of morphia acetate or morphia hydrochlorate, from $\frac{1}{10}$ gr. to $\frac{1}{4}$ gr., is a great aid to the calming and comforting of the patient. I can thoroughly endorse Dr. Clifford Allbutt's commendation of this therapeutic plan which he himself introduced in heart cases. "By the mouth opium is behind other sedatives in value, its use being attended by grave drawbacks, but hypodermically in doses beginning at one-tenth of a grain and gradually ascending to a quarter of a grain if necessary it is a precious means of relief. The physicians who still protest against its use are unfamiliar with the practice. There is no remedy which calls forth so warm a tribute from the patient himself."[6] From these considerations the second practical point I would insist upon is that any sign of rheumatic storm in the heart—a state of things occurring in an apparently chronic phase and obscurely indicated by symptoms—should be treated by placing the patient at rest in bed.

I think it my duty to utter a warning note against the indiscriminate use by the non-medical public of methods of muscular exercise. In many cases of organic heart disease in their truly chronic stages these methods of increasing the physiological activity of the heart-muscle are of very high value, but there is much danger in the case of the rheumatic heart even though the disease may seem to be chronic. If there be the rheumatically swollen heart—a condition of which the patient himself may be unconscious—the use of muscular exercises should be prohibited. To advise these would be equivalent to a direction to a patient with inflamed joints to run. After a period of such absolute rest exercise should be commenced gradually, for too long inactivity is of course harmful, but the question of the duration of the period of complete repose should be left to the medical adviser.

Can medicines aid the absorption of the effusions in and about the heart in the seemingly chronic stages of rheumatism? I think it is generally agreed now that salicin and the salicylates have no directly favourable influence. Indirectly ministering as they undoubtedly do to comfort and well-being in the acute stages and when the joints are painful they are inert as regards any heart inflammation. I have some lingering affection for the old alkaline plan of treatment in the more chronic stages. I prescribe alkalies with no idea of neutralising any morbific acid, but simply because I think they soften membranes, increase osmosis, and thus facilitate the work of the lymphatics. Another plan of treatment which I believe to be of great value is the administration of small doses, $\frac{1}{2}$ gr. three times a day for periods of three or four days together, of calomel. In many cases I have seen what has seemed to me an extraordinary improvement under such plan of treatment.

After the systematic use of the ice-bag has been omitted it seems to be useful to apply iodine in some form over the integument of the præcordia. The painting the surface with liniment or tincture of iodine is a well-known procedure. The method which I adopt of inunction of an ointment of iodide of ammonium is, I think, much to be preferred. A drachm of iodide of ammonium is to be intimately mixed with an ounce of benzoated lard. This ointment is rubbed into the skin over the heart region by means of a piece of flannel or a pledget of cottonwool for two or three minutes night and morning. After the rubbing a piece of cottonwool, flannel, or light tissue is to be kept over the surface. This ointment does not stain the skin like the iodine preparations and it causes little or no irritation though it readily permeates. I think it much to be preferred to our old friend the belladonna plaster and certainly to the sticky, messy, dirty, perforated abominations which some of our patients delight to disfigure themselves with. Moreover, there is no interference with the daily ablutions or affusions with sea-water which are so generally beneficial.

SEPTIC ENDOCARDITIS.

Supposing that our patient with rheumatic antecedents, with the legacy of an old valvular affection which seems to be chronic, fails to respond to the treatment thus briefly sketched out and presents either signs of sinking with gradual failure or occasional crises of dangerous significance, what shall we infer and what shall we do? It is possible that an endocarditis of infective (septic) form has been set up in the areas of the old disease, for it is well known that infective endocarditis especially attacks the portions of endocardium already diseased. In the great majority of cases the advent and course of this almost invariably fatal affection are marked by signs which are acute and not chronic. There are sweatings and rigors with high risings and low fallings of the temperature figured on the chart by extremely acute peaks, and signs of embolism in spleen, kidney, cerebral arteries, arteries of the limbs or of the skin are noticed. Acute signs, however, are not invariable in septic endocarditis. I have observed and recorded cases in which the temperature has been for the most part subnormal, the maximum scarcely ever passing 101° F. and never showing any high peaks. The condition of the patient, however, is one of extreme debility not explained by the physical signs and the pulse is very feeble or dicrotic. I do not intend to enter upon any question of treatment when such a grave condition as this is diagnosed. The disease is almost invariably fatal and perhaps anything I could say might fairly be put down as not practical, and happily these very grave conditions are rare. A case may assume an aspect of extreme danger threatening death from other causes than the complication of infective endocarditis, and it is because I think that therapeutics may be an agency to avert the fatal tendency I shall quote an instance in point. A young American, aged fifteen years, had a severe attack of rheumatic fever. He recovered sufficiently to take a tour in Norway, but five months after the first attack he suffered from rheumatic fever of great severity a second time. Treatment by the salicylates was followed by improvement but there was a relapse after a fortnight. The heart became greatly enlarged, the systoles irregular and ineffectual, and the murmurs first of mitral regurgitation and afterwards of aortic regurgitation were manifested. With great care the

Digitized by Google

patient was brought from Bergen in charge of his physician to London. For many weeks the condition was one of extreme gravity. I observed the case on many occasions. There were successive enlargements of the heart. On many occasions it was noted that the enlargement was followed by recession almost to the normal in a brief period; on one occasion the area of dulness receded from a line considerably to the right of the sternum on the right side and a finger's breadth outside the nipple on the left to the mid-sternal line and a line just within the nipple in the space of twenty-four hours. Then there was for a time considerable improvement and for about five weeks comparative calm, but again the grave signs returned and on one occasion I was called to the patient when death seemed imminent; the area of the heart was much enlarged, the heart-beats were very feeble, the pulse was small and never under 100, the face was pallid, the breathing was short and hurried, and there was orthopnœa but no dropsy. I then determined to try in this acute case a plan which had seemed to me to be of much usefulness in some chronic cases—the continuous galvanic current in the course of the vagus. There was a temporary improvement and we continued the galvanism, administering the current for six minutes three times a day, the current being from eight bichromate cells (three or four milliampères). One electrode (the anode) well moistened with warm saline water was kept pressed over the nape of the neck, and the other (the cathode) was applied in the groove outside the larynx and trachea for six minutes on the right and left sides of the neck alternately. The pulse-rate progressively diminished to 88, 84, and 76 with few variations. The course of treatment was not interrupted for some months, but there was soon sufficient recovery to permit of the patient returning to America. I have seen him here since (in the summer of this year), a hearty, strong, well-developed young man. He has now no cardiac symptoms, though there is the warning note of the murmur of aortic regurgitation.

SPECIAL TREATMENT OF NERVOUS SYMPTOMS.

The third practical point which I would venture to suggest, therefore, is that special treatment of the nervous system in rheumatic diseases of the heart, even those which seem to be chronic is in many cases of very high importance. Of course I have hesitated before concluding that the galvanic current was directly of benefit by influencing the vagus itself. I had, however, observed many cases in which such treatment had given good evidence of success in the treatment of the rapid heart and in the various forms of Graves's disease. Cases in point are detailed in my oration on the Rapid Heart at the Medical Society of London and elsewhere. From observation since of a long series of cases of Graves's disease which have progressed to recovery in a much briefer time than was the case under my former experiences I cannot doubt that galvanism (the continuous not the interrupted current) has a directly favourable effect. I think there is good reason to believe that the involvement of the nervous elements which are the agencies of the cardiac reflexes as well as regulators of the trophic conditions of the heart is to be regarded as a very important consideration for diagnosis and treatment in rheumatic inflammations and dilatations of the myocardium. I am at a loss to explain why one case of pericarditis, of carditis, or of general temporary enlargement of the heart differs so widely in its symptoms from another without assuming that the involvement of the nerve elements plays an important part in the pathogeny. I have seen, as others have, a case in which the physical signs of pericarditis have been fully manifested and yet there has been no dyspnœa and scarcely any subjective discomfort; while in another case the face denotes anguish, the breathing is rapid and gasping, the suffering is intense, and the signs all show that the patient is at the point of death. Considering the marked and agonising dyspnœa of some cases of acute pericarditis Dr. D. B. Lees suggested the questions, "Is there a dextro-cardiac respiratory centre?" and as a consequence, "Is there a dextro-cardiac respiratory reflex?" When there is no disease in the lungs and little or no defect in the aeration of the blood how shall we explain the very obvious dyspnœa unless we conclude that there is an involvement of the nervous mechanism? The late Dr. Sturges pointed out in his Lumleian Lectures that in the cases mentioned it might be contended that there was not pericarditis alone but carditis with the result that the whole substance of the heart was so weakened that the symptoms in question might be explained by the muscle failure. "But," he added, "the extremity of the dyspnœa would seem better explained by Dr. Lees's view—viz., that there is an automatic reflex from the right ventricle to the respiratory centre, such reflex being called into action by the acute failure of the right ventricle resulting from the inflammatory disease. I consider the observations of Dr. Lees and the late Dr. Sturges of very high importance. It appears to me proved by a strong array of evidence that dilatation of the heart can occur as the direct result of disease of the nervous system. I have observed it when there have been signs of neuritis of the vagus. In the cases in which the heart becomes dilated in the course of Graves's disease the dilatation is probably due to nerve disturbance. In palpitations and the rapid heart it may be concluded that disorder of the vagus is the immediate cause of the symptoms. In many cases of rheumatic heart disease nervous disturbances of the heart become epiphenomena. So it can scarcely be doubted that a morbid irritation conveyed to the vagus centre whereby the control power and the other endowments of the nerve are weakened is in many cases a very important contributory factor to produce the ensemble of symptoms. It seems to me, therefore, that an attempt to influence the vagus by the continuous galvanic current is a very reasonable procedure. Moreover, it is one very easy to accomplish. It is, of course, best that the method should be put in train by an electro-therapeutic expert, but this is by no means essential. The practitioner in attendance can arrange every detail and a nurse or the patient can soon be trusted to do all that is necessary, for the regular employment of the method should be continued for many weeks or even months. I by no means wish it to be understood that this plan of using the galvanic current for increasing the tone of the pneumogastric nerve is the only plan to be adopted for favourably influencing the nervous system in these cases. Moral agencies—the inspiration of hope, the avoidance of depressing emotions, and the inculcation of cheerfulness—are of high value. And when muscular movements are permitted and tentative training has taken place changes of scene and climate and the use of baths and systematic exercises are potent agencies for good. I have said elsewhere[7] that allowance must be made for many fallacies when the estimation of the value of treatment by baths and exercises is attempted. I have given in this communication to-night my reason for believing that enlargements of the heart may occur and recede in a way which may be independent of treatment and I have cautioned against the danger of pursuing any plan of muscular exercises when rest is of paramount importance. Nevertheless, when all these logical deductions are made, I cannot but be convinced that in many cases systematic baths and exercises and the careful following out of a plan of treatment such as that of Dr. Blanc of Aix-les-Bains or that of Dr. Schott of Nauheim are of great therapeutic value. I feel it only right to state my opinion that there is not infrequently manifested nowadays an influence which works much for evil in disturbing the rational treatment of chronic heart disease. It is the influence of the irresponsible third person. I will explain what I mean in the forms of hypothesis and parable. A patient has experienced an attack of rheumatism with heart involvement and under the conscientious care of his medical attendant has entered into convalescence. He or she meets the irresponsible third person who says: "How very ill you are; have you tried the barium and gold treatment?" "No." "Then your doctor cannot know anything about your case. You must go to my doctor who knows all about the barium and gold treatment." Or it may be, "Has your doctor ordered you to Paradis-les-Bains or Weissnicht-wo? Oh! you must go to a doctor who will be sure to order you to go to Paradis-les-Bains or Weissnicht-wo." I am sure that those phenomena of interference are not merely visions of the mind but are distinct dangers to good progress in therapeutics. The lay public are apt to be captivated by fashion in matters medical. They hear of a remedy or a given plan of treatment and their enthusiasm gets the better of their discretion. Their knowledge is and must be superficial. They reason from the supposed remedy to the disease, not as the conscientious medical man does—from the disease to the remedy. It is the medical man's duty to keep himself abreast of therapeutic science. He has already in all probability duly

[7] THE LANCET, March 26th, 1898.

Digitized by Google

estimated the prospective value of the means of treatment suggested by the irresponsible third person. If he has not suggested them it is because he thinks them unsuitable to the given case. To the irresponsible third person every case presenting symptoms of heart disturbance is a case of heart disease to be treated by some blatant method for the cure of heart disease. The intricacies of morbid processes involving the heart are of course unknown to the irresponsible third person. Even in the case of the rheumatic heart which I have attempted to sketch out to-night there is much that is intricate and perplexing and the conditions for treatment are multiform. In other cases in which not only the rheumatic changes but the influences of diseased vessels, of degenerations, of the diseases of maturity and more advanced age are to be considered the conditions are more complex still. A disturbance of the well merited confidence between patient and medical attendant works banefully for the former and very often the consultant who has thus been patronised by the irresponsible third person feels himself in an undesirable position, for the facts are withheld from him and the previous history of the patient as offered to him is vague or garbled.

Let me conclude by saying that it is the duty of any practitioner who observes a case of rheumatic heart disease, however chronic, to guard his patient against the subtle future dangers of his malady. It is incumbent on him to make himself acquainted with all the therapeutic means which the present state of science indicates. I think it was Sydenham who said to a lady patient—"Madam, you are entitled to my brains—to all my brains." The medical man must employ such means as are sanctioned by practical experience according to his own discretion without being led away by quasi-scientific will-o-the-wisps. The path is not always easy to find and light from many sources is to be sought for, but the rule is a good one: "Turn to the right and keep straight on."

FOUR CASES OF INSANITY AFTER INJURY TO THE HEAD, WITH OBSERVATIONS RELATIVE THERETO.

BY EDWIN GOODALL, M.D., B.S., M.R.C.P. LOND.,
MEDICAL SUPERINTENDENT JOINT COUNTIES ASYLUM, CARMARTHEN.

THE value of statistics as to the frequency with which insanity follows upon injuries to the head is much impaired by the consideration that cases of injury to the head are mostly lost sight of after surgical treatment has ceased. Unless the mental disorder follows immediately upon the blow it may fail to be recorded. But cause and effect can in this instance be separated by a wide interval of time. With due regard to this limitation in value of statistics in the particular case in point reference may be made to the figures obtained from a German official report upon the war in 1870-71,[1] which are still probably the most instructive available, being based upon so great a material. Briefly, mental disturbance (insanity) occurred in 0·15 per cent. of the cases of head injury. A particularly instructive series of figures has of late been published by Stolper,[2] the patients being healthy men employed upon a large works, whose personal circumstances were to some extent known to the officials, whose injuries were sustained and treated at the works and whose subsequent history was known to an unusual degree. Out of 981 cases of head injury amongst these workmen 12 (or 1·22 per cent.) presented symptoms of mental disorder which could be attributed to the injury. The same writer has collected data upon the subject under consideration from various authors, from which some estimate may be made as to the percentage of cases of insanity in which the malady is referable to injury to the head. The sum total of the cases of insanity dealt with by the various writers is 18,606, and an injury to the head is set down as the cause in 480, or 2½ per cent., of these. The statement will no doubt be generally endorsed that cases of mental disorder arising in consequence of head injury in adults with no predisposition, as far as inquiry can ascertain, to such disorder are rare. I desire briefly to record 4 cases of insanity following upon blows on the head which were admitted to the Joint Counties Asylum, in 3 of which the personal and family history were negative as regards mental aberration and the disorders which are frequently associated therewith.

CASE 1.—The patient was a man, aged twenty-nine years. There was no family or personal history of insanity or allied disorders. No congenital mental deficiency was observed. He was temperate and quite well and working up to the date of the accident. Six weeks before admission he received a kick from a horse on the left mastoid process which rendered him unconscious. There were symptoms of severe concussion and bleeding from the left ear. He came round gradually, but a general dulling of faculties remained. Gradually symptoms of mental aberration became more pronounced; there were delusions of suspicion and then violence was exhibited. He became very restless, entirely "lost" and incoherent and unable to understand what was said to him. Ultimately he was quite unmanageable and was transferred to the asylum. Before this complete paralysis of the left facial nerve was noted by his medical attendant. On admission (August 26th, 1892) the patient was noted to be entirely incoherent with loss of memory and inability to orientate himself; he resisted everything done for him, was most restless, and unable to attend to his personal needs. He took no notice of remarks addressed to him but kept up a meaningless jargon—"acute confusional state." Physically the patient was pale and thin; there was a considerable scar over the left mastoid process, complete left facial paralysis, the tongue protruded notably to the right side (i.e., towards the healthy side of the face), and the right hypoglossal was apparently paralysed, the lesion affecting the left cortical centre (?). (Dr. Lord, Hanwell Asylum, confirmed the observation as to the tongue.) The hearing was very defective on the left side and sound was not conducted by the bone, the auditory nerve being involved. Later, when the patient came to himself, he complained of a difficulty in deglutition, for which possibly a lesion of the glosso-pharyngeal nerve or nerves may have been responsible. No other cranial or other nerve was found to be affected. There were no spinal symptoms. The patient remained in the same condition until Sept. 11th following. Marked delusions of suspicion then developed but were very transient and he began to brighten up. He subsequently described how he came to his senses about the 18th, and by the 25th he appeared to be quite rational. He could remember nothing whatever of events subsequently to the kick; from that date (July 12th) to Sept. 18th was a complete blank. He "woke up" to find himself paralysed over the left half of his face and with a difficulty in swallowing. The patient was discharged recovered on Oct. 12th, 1898, after from six to seven weeks' residence in the asylum. The condition of the face and tongue and of deglutition were unchanged. When last heard of, one month after discharge, he was well and at work.

CASE 2.—The patient was a man, aged thirty-five years. There was no family or personal history of insanity or allied disorders. There was no congenital mental defect. He was temperate. Ten days before admission he received a very severe blow on the left frontal region from a revolving crane handle. The outer table of the bone was felt to be fractured by the medical attendant. The patient was unconscious for a quarter of an hour after the blow and never spoke rationally again before removal to the asylum. There was slight bleeding from the left nostril. His medical attendant described him as being in a state of "cerebral irritation" for forty-eight hours after recovering consciousness. There were slight twitching of the right arm and leg, with some dilatation of the left pupil, and raised temperature. At the end of forty-eight hours he could be recalled to himself; he complained much of pain over the left frontal region. Symptoms of mania then developed and on June 30th, 1894, he was removed to the asylum. On admission there was great incoherence with repetition of words and much motor restlessness; his attention could not be gained and mistakes of identity were numerous, with failure to orientate himself in time or place—a state of subacute mania, with much mental confusion. Physically the patient was healthy. The left pupil was the larger, but reactions were normal in both. There was a recent scar over the left frontal eminence 1½ in. long. The mental condition persisted, with exacerbations of

Digitized by Google

acute excitement, until July 15th of the same year, when he became more maniacal — destructive, stripping himself naked; he was very talkative, with much repetition of phrases. After a few days he became quieter and on July 22nd was reported as much improved. He was sent out to work in the grounds, and convalesced rapidly. His memory was impaired. He was discharged recovered on August 30th, 1894, after two months in the asylum. He resumed his work. When last heard of, a year after the accident, he was quite well and working.

CASE 3.—The patient was a man, aged thirty-four years. There was no family or personal history of insanity or allied disorders. There was no congenital mental defect. He was temperate. Five weeks before admission a topmast fell and struck his head. His wife stated that he was unconscious for three days and "bled from the ears." Subsequently he complained much of pains in the head, suffered from insomnia, and became very restless and incoherent with indistinct utterance. The patient was admitted to the asylum on July 5th, 1897. Upon admission he was noisy, requiring a sedative at night, tearing, restless, unable to fix his attention, and his comprehension was very limited. In replying he often failed to find words, stopped short, and looked puzzled and confused and was much annoyed at his inability to express himself. He had hallucinations of hearing and probably of sight. He talked incoherently to himself for long periods. He made many mistakes in identity. He had no notion of time or place. There was marked intellectual disturbance—"an acute confusional state." Physically he was healthy. He continued in the condition described above during July, becoming, however, gradually more self-satisfied and elated. At the close of July he became hypochondriacal and remained so for most of August. Early in September he improved greatly and could be employed. He was discharged recovered on Oct. 16th, 1897, rather more than three months after admission. He visited the asylum about a month after discharge and appeared to be quite well; nothing has been heard of him since.

CASE 4.—The patient was a man, aged fifty-six years. There was no family history of insanity or allied disorders. There was no congenital mental defect. He was of doubtful temperance. He was in this asylum in 1866, admitted in May, apparently in a state of mania. He was discharged in September of the same year recovered. He has since been employed and earning his living. Eight weeks before admission he received a kick from a horse which rendered him unconscious for an hour. According to his medical attendant the frontal bone was fractured. He began to wander about, became threatening, refused food, and finally developed symptoms of mania with marked incoherence. He was admitted to the asylum on Feb. 1st, 1898 (nearly thirty-two years after the date of his previous discharge). The mental state on admission was one of mild mania—great incoherence and loss of attention-power. Physically he was healthy. There was a healing scar between the eyebrows, the seat of injury. Improvement began in March following admission and was progressive. He was discharged recovered on July 2nd, 1898—five months after admission.

The above four cases have certain features in common—namely, there was no heredity of insanity or allied disorders known of; no previous history of mental trouble in the individual except in the last case (thirty-two years before); the patients were healthy and temperate (excepting the last case, in which this was doubtful); the injury was a severe one and the skull was fractured in probably three of the cases; insanity in each case supervened practically immediately after the period of unconsciousness which followed the blow; the mental state was one of mania, fairly acute, with much incoherence and mental confusion; it was of short duration and all were discharged recovered and resumed work. The literature on the subject goes to show that when insanity follows forthwith upon a head injury the latter is usually of a decidedly severe kind. Most writers note a considerable similarity in the mental symptoms in different cases in adults. The condition is commonly one of mania in greater or less degree, or there is a confusional state, with great incoherence and less excitement. Rapid convalescence is often noted, though some intellectual defect may remain after the symptoms of insanity necessitating confinement have passed. On the other hand, it is well known that paralytic dementia may be occasioned by cranial injury.

Carmarthen.

THE

INOCULATION THEORY OF MALARIAL INFECTION.

ACCOUNT OF A SUCCESSFUL EXPERIMENT WITH MOSQUITOES.

BY DR. AMICO BIGNAMI,

PHYSICIAN TO THE HOSPITAL OF SANTO SPIRITO, ROME; UNIVERSITY LECTURER ON PATHOLOGICAL ANATOMY.

(*Continued from p. 1463.*)

THE first experiment was made with G. N——, an epileptic patient in the wards of the Hospital of San Carlo, and with another epileptic patient of whom I have kept no record because he remained under observation only a very short time. G. N——, a robust young man who suffers from attacks of epilepsy at long intervals, has been for about two years in the Hospital of Santo Spirito, where he assists the nurses in attending to the other patients. He has never had fever nor has he ever resided in malarious places. This man and the other of whom I have spoken were exposed for three days to the bites of mosquitoes taken from Porto where they were caught in the adult state. But as in this first experiment I only succeeded in obtaining a small number of these diptera and the bites were very few I resolved to adopt another plan in my next experiments. I may note in passing that this experiment was commenced in precisely the same manner as that which later gave a positive result and that I stopped it solely on account of the impossibility of obtaining sufficient material.

In order to secure an abundant supply of mosquitoes I resolved to procure their larvæ which are found in immense numbers in the stagnant pools of the Campagna. These larvæ were brought to me in glass vessels which were opened in the mosquito-room. In a few days the production of mosquitoes was such that they might be counted by hundreds. The supply of water with its freight of larvæ was renewed every four or six days by the help of an employé from our Institute of Comparative Anatomy who collected the water either at Porto, near Fiumicino, a place, as I have said, of highly malarious character, or near Carroceto, an isolated station on the Anzio line infested by malaria of a bad type. I obtained in this way the means of maintaining a most abundant supply of mosquitoes for a long time in the conditions most favourable for ascertaining experimentally whether the bites of the variety or varieties of insects thus hatched out were capable of affecting man injuriously.

The experiment was begun in this manner only upon G. N——, who slept in the mosquito-room from August 8th to Sept. 22nd of this year under my constant supervision. He was very much bitten. On August 22nd he felt unwell with a sense of chilliness, and the temperature rose at 8 A.M. to 37·3° C. (99·1° F.), and at 1 P.M. to 37·4° C. (99·3° F.). At 3 P.M. it was 37·2° C. (99° F.), and on the following days it stood at 37° C. (98·6° F.) in the afternoons until the 29th, after which it remained constantly below 37° C. Except for this slight elevation of temperature, lasting, one might say, for only one day, and commencing with chilliness and headache, there was no further sign or symptom of illness, and up to this moment the man remains perfectly well. Naturally, on August 22nd and the following days examinations of the blood were made with great care and diligence, without its being possible, however, to discover any parasites. Some specimens of the hatched mosquitoes were preserved in order that the species might be identified afterwards.

The second experiment was commenced on August 24th on another subject, A—— S——, who had never had malarial fever and who had been for six years a patient in the hospital in the Santa Maria section which is directed by my colleague, Dr. G. Bastianelli. S—— had thus for a very long time been continuously under the observation of a physician who has for many years made a special study of malaria. I cannot but dwell upon this fact since it is of the utmost value in freeing the experiment from a source of serious error. In order likewise to be prepared for possible objections I obtained a complete history of S—— from his earliest years until he entered the Hospital of Santo Spirito and came under our observation there. From this it appears that he had never suffered from malarial fever at any period of his

Digitized by Google

life. He was admitted to the Hospital of Santo Spirito in the beginning of October, 1892, and since then he has presented no other symptoms than hemianæsthesia, neuralgic pains in the joints, volitional tremor, and simple polyuria which at times was slight and at other times very severe. His case was thus a chronic nervous one the exact diagnosis of which it is not necessary here to discuss.

With this subject, then, the second experiment was begun on August 24th of this year and carried out in the same manner as the preceding one. S—— slept in the mosquito-room till Sept. 19th. During all this time the supply of mosquito larvæ obtained from the stagnant pools at Porto and brought to Rome in glass vessels was renewed from time to time at intervals of from four to six days. Only once was the supply obtained elsewhere—namely, from a place between Maccarese and Ladispoli. A very abundant provision of mosquitoes was thus secured and the patient was very much bitten. S—— remained well up to Sept. 10th, when he began to suffer from headache in the morning and malaise. On Sept. 10th the temperature rose to 37·2° C. (99° F.) and then until the 17th it remained normal, when it again rose to 37·3° C. (99·1° F.) and the patient felt ill, complained of severe headache, and had a sense of chilliness. On the succeeding days the temperature did not rise above normal, but the feeling of malaise continuing, with headache and a suffering aspect, the experiment was stopped on the 19th and the patient returned to sleep in the ordinary ward where he soon became perfectly well.

The examination of the blood for malarial parasites, made with every care, especially during the last few days, gave a negative result. Some specimens of the mosquitoes hatched rom the larvæ were preserved for identification.

The result of the experiments so far described being negative (except for the slight elevations of temperature which I shall deal with later) various speculations naturally arise in the mind. Supposing it to be true that malaria may be inoculated on man by mosquitoes the non-success of this experiment might have been due to want of susceptibility in the individual experimented upon. Nor is this an improbable explanation, for not only is it well known that there are certain persons who may remain for more than a month in a highly malarious locality without contracting malaria, but there are some individuals (as Celli's experiments have shown) who, even when inoculated hypodermically with blood containing æstivo-autumnal parasites, do not take the infection. Now, we know that there is held to be no surer way of producing malaria in healthy persons than by thus injecting malarial blood. On the other hand, we might suppose that the mosquitoes employed in the experiment although taken from malarious places did not happen to contain any malarial parasites or even that they did not belong to a variety or varieties adapted to act as hosts to the parasites. Such explanations appeared to me all the more likely in view of the important observations of Ross[1] who in the series of researches already referred to only found the developmental forms of his Proteosoma coccidia in one particular species of the mosquitoes which had bitten birds infected with proteosoma—to wit, in the grey mosquito.

But this last hypothesis was rendered more than likely in consequence of the observations of Grassi whose article appeared at the end of September when my experiments were already at an advanced stage. Grassi established the fact that in malarious districts certain species of mosquitoes exist which, according to his researches, are not found in healthy places. Now, if it be mosquitoes which inject the malarial parasites into man it is evident that they will in all probability be of those species which, according to Grassi, are peculiar to malarious places. Hence it was necessary to repeat the experiment, procuring for the purpose first of all those very species and, since it is difficult to obtain any considerable quantity of their larvæ, to collect from some malarious place in the Campagna the greatest possible number of adult mosquitoes—in fact, to repeat the experiment in the same manner as that in which I had gone to work in the first instance when for want of material I was not able to continue it for a sufficient length of time. The collecting was done at Maccarese, where by Grassi's instructions one of the employés at the laboratory of comparative anatomy was stationed who every day sent a supply of these diptera to the Hospital of Santo Spirito, where they were set at liberty in the mosquito-room as formerly.

[1] Report of the Cultivation of Proteosoma-Labbé in Grey Mosquitoes (Calcutta, 1898).

Thus was begun on Sept. 26th the third experiment. S——, who was by this time completely recovered from the indisposition following upon the preceding experiment, again consented to be the subject. I could not succeed in finding anyone else intelligent enough to understand the importance of the test and so self-denying as to submit to it. Along with S—— there slept in the mosquito-room another patient with nerve disease who, like S——, had never had malaria nor, as far as he was aware, had ever been exposed to the infection. And for a couple of nights a third patient, also a nerve case, slept in the room, but with this man the experiment was not continued. On Oct. 3rd I was obliged for want of new material to suspend the experiment. On the 10th it was again resumed, still with mosquitoes from Maccarese. From the 10th till the 14th there was an abundant supply of mosquitoes. On the 14th Sola complained of malaise and headache, on the evening of the 16th (at 6 P.M.) his temperature was 37·1° C., and on the following days he felt better. From the 17th to the 21st there were but few mosquitoes left in the room; nevertheless both patients showed evident signs of having been bitten. From the 19th to the 23rd no fresh mosquitoes were brought; on the 23rd there was a new but only a small supply. From this date onwards until the experiment came to an end there were but very few mosquitoes in the room; the patients were, however, certainly bitten. During the last days of October S—— complained of malaise and headache. On Oct. 31st his temperature showed a slight elevation to 37·2° C. (99° F.). On Nov. 1st at about 3 P.M. he was seized with severe shivering which lasted till 5 P.M., the temperature rising rapidly to 39° C. (102·2° F.); between 9 P.M. and 10 P M. he again experienced a sense of chilliness. The fever continued all night. On the next morning (Nov. 2nd) the temperature was somewhat lower (38·2° C.), but it rose again in the afternoon to 39 3° C. (102·7° F.). The patient was agitated; he complained of very severe headache but did not present any grave symptom. About 11 P.M. he again had the sense of chilliness but only for a short time. During the night of Nov. 2nd the temperature remained at 39° C. (102·2° F.) and on the morning of the 3rd it rose again to 40·4° C. (104 7° F.), the patient being in great agitation and suffering. During the afternoon the fever showed signs of abating and there was slight perspiration. At 5.15 P.M. a hypodermic injection of quinine was administered (15 gr.), and this was repeated (in the same dose) during the night. The fever subsided and at 8 o'clock on the following morning (Nov. 4th) the thermometer registered 36·7° C. (98·1° F.). During the next few days the administration of quinine was continued, the patient having a slight elevation of temperature which did not, however, reach 38° C. (100·4° F.), except on the 6th. From Nov. 7th onwards the patient was entirely without pyrexia and he rapidly recovered his appetite and went on regaining his strength.

A careful examination of the blood made on Nov. 2nd gave a negative result; in spite of the most diligent search not a parasite was to be found. On the morning of Nov. 3rd I found young amœboid parasites, few in number, mobile or discoid and without pigment, with the appearance characteristic of those of autumn fevers. These forms went on increasing in number during the course of the day and in the afternoon they were present in considerable quantity, some of them presenting pigmentation at the edges, the pigment being in very fine granules. Before the quinine was given dry preparations of the blood were made by fixing with absolute alcohol and staining by Romanowsky's method and with hæmatoxylin and eosin. In these preparations the parasites present the characteristic annular forms with the particle of chromatin stained in the typical way.

Thus there was produced experimentally in the case of S—— a grave form of malarial fever with the temperature curve which is often seen in a primary æstivo-autumnal attack. The fever having begun sharply continued with slight intermissions from Nov. 1st to the 3rd, when it showed signs of abating towards evening and the quinine was administered. The parasites found in the blood belonged to the æstivo-autumnal variety, so that, keeping this in mind and also the course of the temperature, we may conclude that the continuous curve of the latter would, but for its interruption by the quinine, have developed into that of an autumnal tertian fever.

It is perhaps the first time that in a primary æstivo-autumnal infection contracted in the natural way the examination of the blood has been made from the beginning of

Digitized by Google

the fever. It is noticeable that the parasites were found after about forty hours, at first few, then rapidly becoming more numerous.

It seems to me and to all those who watched the experiment that it was conducted in such a manner as to meet all possible objections. Let me repeat that S—— is a man of robust constitution, despite his nervous malady, who, as a minute inquiry shows, had never in all his life suffered from malarial fever and had not for the last six years left the Hospital of San Spirito, where he had all that time been under the observation of Dr. G. Bastianelli. The room in which the experiment was carried out forms one of the annexes of the San Carlo ward, where none of the physicians have ever known an autochthonous case of malarial fever to occur nor has malaria ever been known to originate in any of the neighbouring houses.

The objection that the experiment cannot be considered as conclusive because it was made in Rome, where some persons imagine there is always danger of contracting malaria, can only have an appearance of value for those who do not know Rome and the distribution of malaria in our district, for all the local medical men are well aware that although there are some malarial foci at certain points of the outskirts the city itself is quite healthy and long experience has shown that no one at any season ever contracts the fever there. The Hospital of San Spirito is so situated as to preclude any suspicion of the kind. Now, in a room of this hospital a patient contracts malarial infection produced by æstivo-autumnal parasites with a continuous fever and symptoms of a nature to render necessary the prompt administration of quinine—one of those fevers, in fact, which are commonly contracted by the labourers in the Roman Campagna in the summer and autumn months and which, as we know, usually begin with the temperature curve described by Marchiafava and myself as typical of the summer tertian fever or even with a continuous curve. This fever, then, identical with those prevalent at Maccarese, was contracted by S—— in surroundings in which there was neither the water nor the air nor the soil of Maccarese, but *only its mosquitoes*. Hence we are forced to the conclusion that this fever was actually inoculated by these mosquitoes. In this manner I obtained an experimental production of malaria under conditions narrowly circumscribed, a healthy room being transformed into a malarious environment by introducing into it mosquitoes taken from a malarious locality. The conditions under which the experiment was conducted were, in short, such that I cannot conceive of any source of error which can have crept into it to vitiate the result, and it is clearly impossible to draw from it any other conclusion than that the fever contracted by S—— was inoculated by the mosquitoes. The result obtained constitutes, in my opinion, a positive proof which of itself and *per se* is sufficient to furnish a secure basis for the theory of inoculation.[2]

But by which species of mosquito was the fever inoculated? To this inquiry the experiment, from the way in which it was conducted, does not give an answer as conclusive and as free from objections as it gives to the fundamental question itself. I have said that some specimens of the mosquito with which the various experiments were carried on were preserved for identification and classification. Professor Grassi has found that some of the specimens hatched from larvæ with which the first experiments were made belonged to Culex pipiens. During the third experiment, Grassi being in Rome, some of the mosquitoes were sent to him every time a batch was received at the Hospital of Santo Spirito. Amongst these, captured in the adult state, Grassi identified the Culex penicillaris, the Culex malariæ (so-called), and Anopheles claviger; but of this last species only a few individuals were sent and only on one occasion during the course of the experiment. It follows therefore that S—— was bitten by the Culex pipiens from August 24th till Sept. 19th and by the other three species, especially by the two first, from Sept. 26th until the end of October.

According to Grassi it may be taken for granted that when the experiments were made with mosquitoes hatched from larvæ collected in the Campagna the insects obtained would be the Culex pipiens, because the larvæ of this species are found in great swarms and are in consequence easy to collect, while the larvæ of the other species named are found with more difficulty and not in swarms. I believe, however, that while the Culex pipiens no doubt predominated in the first experiments one cannot be quite as certain that there were not present in smaller quantity individuals of the other species which also frequent the malarious parts of the Campagna. Hence we cannot exclude with absolute certainty the possibility that in the second experiment there may have been along with the Culex pipiens also some individuals of the same species which were employed in the third experiment. On the other hand we cannot with certainty exclude the possibility that the infection may have come in the period between August 24th and Sept. 19th; indeed, cases are known (and I myself have several times met with such) of individuals in whom the fever began even more than a month after they had left the malarious locality. But it is certainly much more likely that the infection came in the last period of the experiment—that is to say, while the mosquitoes were being brought from the Campagna in the adult stage—and the prevailing species were those which Grassi has found only in malarious localities.

Grassi, in the study which he made during last summer of the distribution of mosquitoes in malarious and non-malarious localities, came to the conclusion that in malarious places in addition to the species which are found in non-malarious districts there are others which are absolutely unknown in these latter. In non-malarious districts the predominating species is the Culex pipiens; in malarious places, on the other hand, are found the Anopheles claviger (maculipennis), the Culex penicillaris, and other species, which therefore appear to have an intimate relation with malaria. One of these species, apparently not yet described, Grassi found at Maccarese and he named it "Culex malariæ."

The coincidence between the distribution of malaria and that of certain species of mosquitoes, especially the Anopheles claviger and the Culex penicillaris, is a fact of great importance which naturally lends itself to various interpretations. The opponents of the mosquito theory, for example, might hold that the same conditions which permit the development of certain species of mosquitoes in particular places which are malarious and not in others which are healthy likewise permit in the first-mentioned the development of the malarial parasites; hence the coincidence in their distribution. But when once it has been *demonstrated that malaria is inoculated by mosquitoes* then only can it be affirmed that between the species found by Grassi in malarious places and malaria there must exist an intimate causal relationship. The demonstration of the fundamental fact having now been given, as we have seen, everything points to the probability that in my experiments the mosquitoes which inoculated the malaria are to be found among the Culex penicillaris, the Culex malariæ, and the Anopheles claviger. This last species was represented by only very few individuals. It is thus probable that the greatest importance attaches to the Culex penicillaris or the Culex malariæ or perhaps to both of these species.

But on this aspect of the question I shall dwell no longer. My experiments were directed towards ascertaining whether malaria is inoculated by mosquitoes, and while they have yielded a decisive result as far as that fundamental problem is concerned they cannot have any other value in regard to the remaining questions than as guides towards their solution. But from this point of view they give an experimental support to the idea that the Culex pipiens is innocuous and appear to indicate the Culex penicillaris or the Culex malariæ as most probably the intermediate host of at least one species of malarial parasite.

Here it may be demanded why it was that fever did not develop in the other individuals who sojourned for so long in my "camera malarica"? The answer is obvious, that while instances of absolute immunity from malaria in our race is extremely rare one nevertheless meets very frequently with individuals who even in districts of a highly malarious character are seized with their first attack of fever only after a sojourn of some months' duration. This explanation will apply to the immunity enjoyed by the second subject who was placed under exactly the same conditions as S—— during the whole course of the third experiment. On the other hand, the negative result of the first two experiments made in August and September is to be explained in all likelihood by the fact that the subjects of them were exposed

[2] An investigation might also be made as to whether mosquitoes which have bitten malarious persons are capable after a certain time of inoculating a healthy individual with malaria. This is, however, a separate experiment. My idea was, on the other hand, to discover whether mosquitoes in the native state, so to say, in which they are procured from the Campagna, could convey infection to a healthy person.

Digitized by Google

exclusively, or almost exclusively, to the bites of the Culex pipiens. From this point of view my two first experiments, carried out under conditions identical with those of the third, except in regard to the species of mosquito employed, served up to a certain point as controls to the last.[3]

It might also be asked what explanation can be given of the slight elevations of temperature with sense of chilliness, headache, and general malaise, noticed in the subjects of the first and second experiments towards the end of the periods over which they extended? I consider that they had probably nothing to do with malaria, since the clinical record as well as the minute examination of the blood tends to exclude the supposition. But it has been observed that some individuals are subject to slight and transient elevations of temperature when exposed to the bites of mosquitoes. Now, it must be remembered that these patients were very severely bitten on account of the enormous number of diptera developed from the large supplies of the collected larvæ.

Is the bite of certain species of mosquitoes the only means, it will next be asked, by which the malarial parasites penetrate into the human organism? In other words, is malaria only contracted by inoculation? So much is certain—viz., that *inoculation is up to the present the only means for which experimental demonstration has been obtained.* But to demonstrate experimentally that the fever cannot be contracted in other ways a long series of researches would be required, conducted in the manner indicated by me at the commencement of this paper. It would be necessary to observe how a large number of persons are affected by malaria when they are all maintained under the same conditions of life in some highly malarious centre, a portion of them being protected and another portion unprotected against the bites of mosquitoes. In this manner an experimental solution of this problem also may possibly be found.

In the meantime we are justified in considering malaria as exclusively a disease of inoculation. I had already arrived at the same conclusion as I have now reached in the direct way by a process of exclusion. By arguments derived from epidemiology and pathology I excluded the theories of air- and of water-conduction and further rested my contention upon certain facts of analogy. The arguments based upon analogy, as I pointed out in my first paper, are chiefly taken from what is known of the "cattle fever of Texas" which is inoculated into the animals by a tick (Boophilus bovis, Riley). The very important experiments of Smith and Kilborne demonstrate, in fact, not only that the young ticks artificially reared inoculate the infection when they are placed on susceptible animals, but also that the tick is *necessary* in order that the infection may be transmitted. I believe it may be safely affirmed that all the facts known up to the present regarding the biology of the parasites allied to those of malaria favour the idea that infection is conveyed by only one way and introduced by only one method.[4]

And now, having securely established a starting point for our researches, a long series of problems opens up for solution. Under what form are the malarial parasites present in the mosquito? Is it the same species of mosquito which inoculates man with various forms of malarial fever, or are there different species, as the investigations which have so far been made would lead us to believe? And from where do these diptera get the parasite? Do they perhaps take it from man, as might be supposed from analogy with what is known of the fever of Texas, and does the malarial parasite complete one life-cycle in the mosquito in the same way as it completes the other in man? Or, on the other hand, as Manson[5] supposes on the strength of Ross's researches with birds infected with proteosoma, must the parasites be regarded as, above all, parasites of certain species of mosquitoes by which they are only accidentally inoculated into man? Regarding these and other questions, investigations are now being prosecuted. For the present I shall content myself with observing that whatever may be the answer to these questions once the great fundamental problem of how the fever is taken has been solved the practical question of prophylaxis straightway emerges from the uncertainty which now surrounds it, and I do not doubt that it will be easier to find a means of defence against the enemy when we know by what way he comes and by what weapons he assails us.

To sum up, malaria is a disease which is contracted by inoculation—a fact of which we have now obtained the first experimental proof, since we have seen that an individual who has never had malarial fever by sleeping in a healthy place where no one had ever previously taken fever may sicken with malaria of a grave type if bitten by certain species of the mosquito brought in the adult state from some distant locality of highly malarious character. Further, everything points to the conclusion that inoculation is the only mode by which infection is acquired, since air and water as carriers of infection may be excluded and because arguments based on analogy all tend in the same direction. This much at any rate we can assert—namely, that inoculation is the only mechanism of infection which has been demonstrated experimentally.

Institute of Pathological Anatomy of the Royal University of Rome.

(To be continued.)

[3] I say this with reserve because one cannot yet exclude the possibility that even the Culex pipiens may be infective in some malarious places.

[4] I have not neglected to make other investigations with the object of finding fresh facts for or against the possibility of the *inhalation* theory. It has been objected against the air-conduction theory that the malarial parasites are so delicate that they cannot resist desiccation. But no one, as far as I am aware, has attempted to ascertain if this really be the fact. In a case of summer tertian fever with very many parasites I removed from a vein by means of a Pravaz syringe about 1 c.cm. of blood and left it to dry in several sterilised Petri's capsules in a very thin layer for about forty-eight hours at the temperature of the air (30° C.) I then mixed it with a normal solution of chloride of sodium at about 37° C. and injected it under the skin of an individual who had not had malaria. This was on August 15th of the present year and up to this time the patient remains perfectly well. Proceeding in the same manner I dried in sterilised Petri's capsules some drops of the splenic contents taken during life from a case of pernicious fever in which there were innumerable parasites in all stages of development, including that of fission. The desiccation this time lasted about one hour and three quarters. I injected the dried blood under the skin of another person who had never had malaria on August 31st. The result was again negative. I do not attach much value to these experiments. It would be desirable to repeat them, varying the conditions. They only show that the malarial parasites which are found in the human body do not resist desiccation even for a short period under the conditions which I have described. I also began other investigations, starting from the assumption, admitted by many, that the germs of malaria may find entrance along with dust by inhalation. In that case they ought to be found, one would suppose, in the peri-bronchial glands of individuals residing in highly malarious localities. I therefore examined, both in the fresh state and with various stains (especially with methylene blue), the contents of the peri-bronchial glands of individuals from malarious parts of the Campagna who died after a short residence in the Hospital of Santo Spirito. I saw nothing, however, to excite the least suspicion of the presence of parasites.

DIPHTHERIA ANTITOXIN IN PRIVATE PRACTICE.

BY E. C. BOUSFIELD, L.R.C.P. LOND., M.R.C.S. ENG.,
BACTERIOLOGIST FOR THE PARISH OF CAMBERWELL.

IN view of the importance of the question I am led to offer a few observations upon this subject suggested by the able and comprehensive paper of Dr. Louis Cobbett in THE LANCET of Dec. 3rd, 1898. It must not be supposed that these observations constitute a claim upon my own part to be regarded as a specialist. My chief reason for offering them is that whilst many tables have been published showing the death-rate in hospitals the records of the use of antitoxin in private practice are few and far between.

My first experience of this remedy dates back to the time when Dr. Klein was investigating the matter early in 1894 on behalf of the Local Government Board. At that time I had a "return" case of diphtheria and Dr. Klein was good enough to furnish me with a quantity of the serum for use in this case. The result was nothing short of a revelation, the temperature fell within nine hours after the use of the remedy and the membrane had disappeared from the throat in twenty-four hours. Since that time I have used no other remedy in the initial stages of diphtheria and have employed it in 33 cases, with one death. This latter was a patient whom I saw for the first time on the fourth day of the disease and who was removed to hospital. Possibly a second injection might have saved this life too.

Of after-effects beyond urticaria I have nothing to relate, and my impression is that even the urticaria was due to the method of preparation of the antitoxin, since I have not observed this symptom for a long time now. Paralyses, never severe, have followed the disease in a certain number of cases, but there is no evidence to show that antitoxin has the power of undoing mischief already suffered by the nerves

[9] Loc. cit.

Digitized by Google

before the use of the remedy. In no case has any local inflammation occurred at the seat of injection. I may remark in passing that I invariably choose the subcutaneous tissue of the abdominal parietes. The skin is loose here, so that the distension caused by the injection gives rise to very little pain, and should any slight local soreness remain for a few days it does not interfere with the patient's comfort in lying down, whilst the comparative thinness of the skin greatly facilitates the operation.

Whilst it is my habit to make a bacteriological examination of the cases of diphtheria which I attend I do not think of waiting for the result before operating. Experience shows that a considerable number of cases occur in which, whilst the clinical signs are somewhat doubtful, the disease responds to antitoxin, so that the latter must be looked upon as a diagnostic agent as well as a curative one. It seldom happens that a second injection is required. In only 2 of my 33 cases has this occurred. One was a case which did not come into my hands until another medical man had stated that nothing more could be done; the other was a very severe case following immediately on an attack of erysipelas not completely recovered from. In both these cases the first injection produced a considerable improvement, but this was not fully maintained, and a second injection was administered at the end of twenty-fours with perfect success.

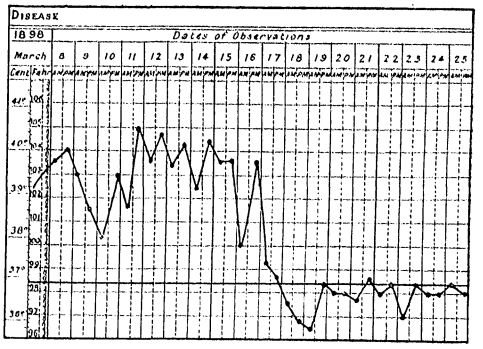
There are several important points with reference to the use of antitoxin which have not received the attention which they deserve. The first is that the remedy should be used immediately the disease is discovered. The statistics of the Metropolitan Asylums Board show that whilst even with the delay occasioned by the removal of the patient to hospital cases injected on the first day show a 4 per cent. mortality, a delay of twenty-four hours causes a rise to 15 per cent., and that this increases at the rate of about 7 per cent. per diem. I contend, therefore, that it is the duty of every medical man to apply antitoxin immediately in every case of diphtheria or suspected diphtheria which he sees, without waiting for the patient's removal. The mere adoption of this plan would probably reduce the London death-rate to one-third of its present amount—indeed, probably much lower. The objection will naturally be made that in many of these cases the expense of providing the remedy would fall upon the medical man. This should be obviated by the action of local authorities. A supply of antitoxin should be kept at some point or points where it is constantly accessible and if necessary the services of a medical practitioner should be available for its administration. There can be no doubt that Dr. Cobbett is right when he asserts that medical men do not in many cases (I fear in the majority) recognise that the agent in question is one which is capable of robbing diphtheria of its terrors and that the evidence of its utility is such that those who do not use it incur a grave responsibility. I should go even further and assert that the responsibility is nothing short of criminal. Antitoxin is no longer upon its trial. Its utility has been proved, and since no other remedy is known to have the slightest direct influence upon this dire disease there is no possible excuse for a failure to try it.

As regards after-infection statistics are at present wanting to enable any direct assertion to be made, but since the membrane clears off the throat within at most forty-eight hours it seems clear that there can be no further growth of virulent diphtheria bacilli and that a week probably represents the outside time during which it is necessary to isolate the patient. In my early cases I endeavoured to persuade the attendants to allow themselves to receive a protective injection, but in view of the shortened period of infectivity I now content myself with ordering the nurse to gargle with Jeyes' fluid 1 in 1000 and to use the same agent 1 in 500 for general disinfection; in either of these strengths it can be readily borne by the skin or even mucous membranes.

In conclusion I appeal most earnestly to my fellow-practitioners to use antitoxin *immediately* in every clear or doubtful case of diphtheria, feeling assured that in no other way is it possible to seriously diminish the mortality and that, as I have said, even the delay of sending cases into hospital means a distinct and decided increase in the death-rate such as no self-respecting or humane practitioner would willingly be a party to. It seems desirable to add that I habitually use, and am entirely satisfied with, the antitoxin supplied by Messrs. Burroughs, Wellcome, and Co., of 1500 units.

Old Kent-road, S.E.

REACTIONS IN CASES OF WOUNDS AND ULCERS TREATED BY OXYGEN GAS.



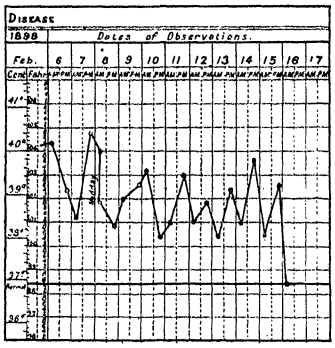
BY GEORGE STOKER, M.R.C.P. IREL.

IT has been observed in almost all the cases treated by oxygen gas that at some time during the treatment, varying from a few days to a few months, a distinct toxic reaction occurs and that from the time of such occurrence the wound or ulcer heals much more rapidly. Out of many such cases a few typical ones have been selected in order to illustrate their toxic reaction and their temperature charts and notes are given below. In considering these cases it must be remembered that in all of them the discharges were carefully examined from time to time and found to contain a pure growth of staphylococcus pyogenes albus, aureus, or citreus. The points of special interest which have been observed in reference to the above are:—1. That healing was not delayed but was accelerated during and after the time the temperature was highest. 2. That the wounds did not become inflamed or dry and the discharge continued healthy. 3. That there was a good deal of inflammation of the lymphatics and some swelling of the glands in the neighbourhood of the ulcer. 4. That in some cases—e.g., Cases 2, 6, and 7—small secondary areas of infection existed where small abscesses formed, burst, and healed rapidly. 5. That in all the cases observed the general malaise or disturbance was small in comparison to the height of the temperature. The tongue remained clean, there was little headache, and no sickness.

Taking the above facts into consideration it is not unreasonable to conclude, as already suggested, that oxygen acts by forming an antitoxin from the secretion of the micro-organisms present in the wound or ulcer. It is possible that the antitoxins which are made by injecting horses, &c., with toxins are formed by a somewhat similar process of oxidation taking place in the blood of the animal so injected. This would further suggest the necessity of preparing an antitoxin for each separate case from its own micro-organisms, especially in more malignant forms, it being presumed that an antitoxin must have a toxin present on which to act or react. Acting on this belief antitoxins have been prepared for many cases by passing a stream of oxygen from a broth culture of the micro-organisms from each case; the broth is then dropped on the wound where it is absorbed. The results of this method have been satisfactory not only in cases of a non-malignant character but also in cases of lupus and rodent ulcer. It is hoped and believed that working in this way and preparing antitoxin as above described that the satisfactory treatment of malignant disease may be ultimately reached.

CASE 1.—This patient had varicose ulcers of both legs of seventeen months' duration. He was treated for several months as an in-patient at a general hospital. Complete

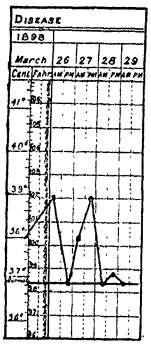
FIG. 1. (CASE 1).



rest, grafting, &c., were tried, but without success. Under oxygen treatment the reaction did not appear till after eight months. He is now quite healed.

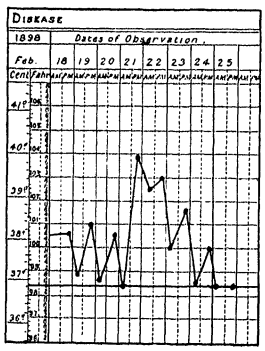
CASE 2.—The patient had chronic ulceration of the right leg of eight years' duration probably the result of hereditary

Digitized by Google



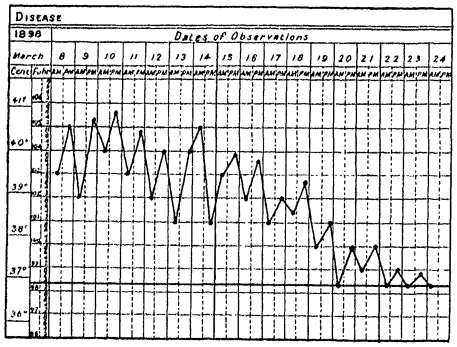
syphilis, he having lost his soft palate at four years of age. Ulceration was very extensive, reaching behind from the apex of the popliteal space to the lower border of the calf in front from above the patella to the front of the ankle. These ulcers are now healed. A secondary abscess formed which is now healing rapidly. Reaction occurred on the ninth day of oxygen treatment.

FIG. 2 (CASE 2).



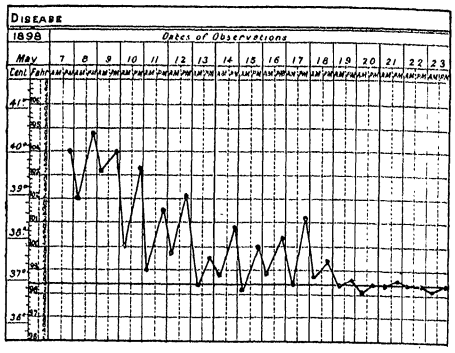
CASE 3.—The patient had an ulcer on the front of the shin of six weeks' duration the result of an accident. She was discharged cured in five weeks, the reaction occurring on the sixteenth day.

FIG. 3 (CASE 3).



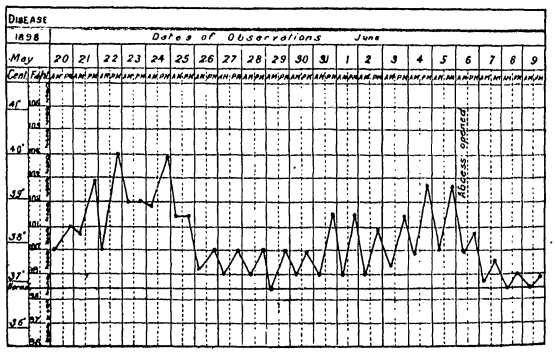
CASE 4.—The patient had two small ulcers on the outer side of the leg above the knee. He also had two long sinuses, one leading inwards and backwards to the apex of the popliteal space and the other upwards on the outer side of the leg. Oxygen was passed through the sinuses by means of a tube and the ulcers were exposed to oxygen in the usual way. The patient made an excellent recovery and now after many months there is no sign of recurrence. Reaction took place on the twenty-second day.

FIG. 4 (CASE 4).



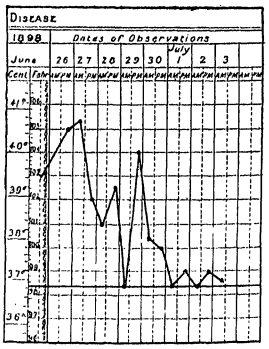
CASE 5.—The patient had chronic ulcers of each leg of eight years' duration the result of an accident. Both legs are now quite healed. The reaction occurred on the fifth day.

FIG. 5 (CASE 5).



CASE 6.—The patient had a very large chronic ulcer of the right leg of eight years' duration. The patient had been treated in various ways, including prolonged rest, but without cure. The ulcer was the result of an accident. The patient is now almost well. The reaction began on the fifth day of oxygen treatment. In this case there was an area of secondary infection.

FIG. 6 (CASE 6).



CASE 7.—The patient had a chronic ulcer on the shin of three years' duration. She had several areas of secondary infection where small abscesses formed but quickly healed again under oxygen. The reaction occurred on the seventh day.

FIG. 7 (CASE 7).

CASE 8.—This patient had two ulcers on the left leg the result of an accident. The ulcers had existed for four years. In this case the reaction took place on the thirteenth day. Both ulcers are now quite healed.

TYPICAL AND SEVERE CASE OF SPORADIC CRETINISM IN WHICH THE PATIENT MENSTRUATED REGULARLY.

BY BYROM BRAMWELL, M.D., F.R.C.P., F.R.S. EDIN.,
PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH; LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE AND ON CLINICAL MEDICINE IN THE SCHOOL OF MEDICINE, EDINBURGH, ETC.

THE chief point of interest in this extremely well-marked case of sporadic cretinism is that the patient who was thirty-six years of age and measured exactly 36 in. in height had since the age of twenty-five years menstruated regularly every month. This is quite peculiar. I am not acquainted with any other case of typical and severe sporadic cretinism in which menstruation has occurred. The notes of the case are as follows.

The patient, aged thirty-six years, was first seen on Jan. 26th, 1895, and was again seen on Nov. 15th in the same year. Her stepmother stated that she had known the patient from the age of three years. She then had a somewhat peculiar look and vacant expression of countenance. Her birth had been unattended with difficulty. During infancy she had several attacks of bronchitis which were supposed to have retarded her development. She did not begin to walk until she was three years old and she had hardly grown in height since that time but had become very much broader. When she was seven years old the patient had an abscess on the outer part of the left leg. She had also twice had a glandular abscess of the neck; the last abscess occurred when she was sixteen years of age. She had never had any of the diseases peculiar to childhood, though she had been exposed to some of them. She had slept, for example, in a room with one of her sisters who was suffering from scarlet fever during the whole course of the disease but did not take it.

The family history of the patient showed that her mother had died at the age of thirty-one years from consumption and that her father had died at the age of fifty-four years from gangrene of the foot following rheumatism. There were six children in the family: (1) a female, now aged forty years, unmarried, and quite well and normal in every respect; (2) a male who died from phthisis at the age of twenty-eight years, a fine, tall man, 6 ft. in height, who had been in the Cameron Highlanders; (3) a female, aged thirty-eight years, married, well formed and of average height but not very strong; (4) a female who died a few months after birth; (5) the patient; and (6) a male who died a few months after birth while teething. There were also six stepbrothers and sisters; all were well developed and strong. No other case of sporadic cretinism or myxœdema had, so far as was known, occurred in the families of either the father or the mother.

The patient's present condition is typical of a marked degree of sporadic cretinism. Her height is exactly 36 in. and her body is very broad; the back is markedly curved in the lumbar region and the abdomen is very large and prominent. There is no umbilical hernia. The facial expression is highly characteristic. The face is swollen and full; the skin of the eyelids is translucent; the nose is squat and broad, pug-shaped; the ears are rather large; the mouth is large; the lower lip is pouting but the lips are not much swollen; the tongue is not protruded between the teeth and, though large, is not proportionately so large as one might expect; the teeth in the upper jaw are all wanting; and the palate is very broad and flat. The head is covered with a profusion of dark-brown hair which is very coarse. Up to the age of twenty-five years it was kept short as her head was scurfy and scaly. Since the patient began to menstruate the scalp had become much cleaner and the hair has been allowed to grow long. The anterior fontanelle is closed; the patient's stepmother says it was very late in closing but she does not remember the exact date at which it closed. The neck is very broad. Enormous fatty swellings are present above the clavicles. I have never seen these supra-clavicular swellings proportionately so large in any other case. There is also some fatty swelling in the anterior fold of the left axilla. The forearms are colossal and the tibiæ are somewhat bent inwards. The hands are enormously broad and large. I have not seen the hands proportionately so large in any other case. The fingers are very broad and flat and the feet are very broad and short. The hands and the feet easily become blue and cold. In complexion the patient is somewhat earthy-coloured. The skin generally is dark, dingy, brownish-yellow in colour, very dry, coarse, and harsh. She never perspires. She is worse in cold weather and her stepmother states that no matter how near the fire the patient gets she is always cold. Her appetite is small and she does not like sweets. The bowels act regularly and medicine is never required. Urination is natural. The nipples and areolæ are somewhat developed and there is a fulness in the position of the breasts. Since the age of twenty-five years the patient has menstruated every month; on one occasion (a year and a half ago) the discharge stopped for three months. There are no pubic hairs. She is naturally of a very cheerful disposition, fond of fun and company, but her intellectual development is that of a child of five or six years. She understands a great deal that is said to her, but her vocabulary is limited and she does not speak much. Before I knew that she was able to understand what was said to her I remarked that she was a comical little person, whereupon she immediately began to laugh. She told me that she was going to a wedding and that she was going to wear a blue dress. She is, it seems, very vain and fond of dress. She sleeps well—in fact, too well.

The following are the exact measurements: height, 36 in.; circumference of the abdomen at the level of the umbilicus, 24 in.; of the chest at the level of the nipples, 22 in.; of the neck over the thickest part of the glandular swellings, 19 in.; of the neck higher up, 14 in.; of the upper arm at the middle, 6¾ in.; of the forearm at the thickest part, 7¾ in.; of the hand, 9⅛ in.; length of the hand from the wrist to the tip of the middle finger, 4 in.; circumference of foot at the thickest part, 8 in.; and length of foot, 6 in.

I did my best to persuade the stepmother to allow the patient to come into the infirmary but she would not consent to this. I then tried to induce her to have the thyroid treatment carried out at home. She consulted with the patient's sister on this point but they both refused to have the treatment carried out. They said that they had known the patient so long in her present condition and were so much attached to her that they would not like to have her changed even for the better.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF DOUBLE EMPYEMA OF THE FRONTAL SINUS WITH ONE INFUNDIBULUM.

BY W. R. H. STEWART, F.R.C.S. EDIN.,
SURGEON TO THE EAR, THROAT, AND NOSE DEPARTMENT OF THE GREAT NORTHERN CENTRAL HOSPITAL; CONSULTING SURGEON TO THE LONDON THROAT HOSPITAL.

A PATIENT, twenty-nine years of age, consulted me about two years ago for stuffiness of the left side of the nose, with a discharge of some duration, and occasional severe frontal headache. Examination showed polypi with an abundant milky-white discharge on the left side. The right side was apparently normal. There was no bulging or disfigurement of the face. The radical operation was explained to the patient, who, however, would not have it done, preferring the milder mode of treatment. The polypi were therefore removed together with the anterior ends of the middle turbinates. A free discharge remained but all sense of stuffiness and headache disappeared. About eight months ago, however, she wished for the major operation as the discharge continued so profuse. All the symptoms pointing to unilateral disease, I operated through the brow incision with a small trephine. The bony septum between the sinuses was found to be situated well over to the left side and was complete with the exception of a small hole posteriorly through which pus was oozing. The septum was removed, but there was so much granulation tissue in the right sinus that I continued my incision down the ridge, across the top of

Digitized by Google

the nasal bones (taking care to avoid the spot where the spectacle frame might rest), and up the other ridge, and the flap was turned up. The bone was then chipped away with forceps until there was space enough to thoroughly clear out the right sinus. The reason why there was no discharge into the right side of the nose was then explained, for with the finest probe I could find no sign of an infundibulum on that side. The sinus discharged through the opening at the back of the septum into the left infundibulum. The usual funnel-shaped india-rubber tube was passed through this into the nose and the wound was closed. The patient did very well.

The points to be noticed in this case are—(1) the absence of the infundibulum on the right side which led me to believe that the right sinus was healthy and did not need interference, there being sufficient disease on the left side to cause all symptoms; and (2) the amount of room gained and the very small apparent scar left by the incision, which I have since employed with success in more than one case of double empyema.

Devonshire-street, W.

PHTHISIS WITH PECULIAR CARDIAC PHYSICAL SIGNS.

BY W. SOUTHWICK WILLMORE, M.R.C.S. ENG., L.R.C.P. LOND.

THE case of phthisis with peculiar cardiac physical signs reported by Dr. Hale White in THE LANCET of Nov. 19th, is of such interest that no apology is needed for recording an exactly similar case which came under my notice a few days ago.

The patient was a soldier and was under treatment in the Royal Victoria Hospital at Netley. He was twenty-seven years of age. When I first saw him a week before his death he was evidently in the last stage of phthisis, with extreme debility, emaciation, cough, and abundant expectoration. Examination showed that the right lung was extensively diseased from apex to base. There were evidences of considerable cavitation at the apex and of a moderate amount of fluid at the base. The left lung was also diseased but in much less degree, the apices only of both lobes giving morbid physical signs. On examination of the heart at first I could make out no impulse and, moreover, there was no cardiac dulness to the left of the sternum. In the usual situation of the apex the heart sounds were very faint, almost inaudible, but on tracing them to the right they became more audible and were of almost normal intensity in the fifth right intercostal space, 2¾ in. from the mid-sternal line; here also a feeble but perfectly distinct impulse could be felt. There was no visible pulsation in any part of the pericardium. The man's condition with distressing orthopnœa did not permit of a prolonged examination, but there was apparently an area of absolute cardiac dulness commencing above at the fourth intercostal space and extending to the right to within one inch of the vertical nipple line, although the pleural effusion and the consolidation of the lung made it very difficult to be sure of this.

My first impression was that the heart had been dragged over by fibrosis of the right lung and pleural adhesions but, considering that the duration of the disease had been only nine months, that there was no retraction of the chest-wall, and that the physical signs were in no way suggestive of pulmonary fibrosis, the case seemed impossible of explanation in this way, and my opinion was that it was a case of dextrocardia. I examined the patient's chest once again before his death and then noted no change in the physical signs. He died on Nov. 15th.

At the post-mortem examination it was found that the heart was of natural size and that it was in no way displaced from its normal position. The condition of the lungs was consistent with the physical signs elicited during life. There were several large cavities in the upper part of the right lung and the whole lung was diseased and partly consolidated, although not completely airless. There were about 15 oz. of fluid in the right chest. The anterior border of the left lung covered completely the anterior surface of the heart nearly to the mid-sternal line.

The intensity of the cardiac sounds in the fifth right interspace in this case, as in Dr. Hale White's case, can be readily explained by the fact that they were conducted through the consolidated lung and perhaps intensified by the proximity of large pneumonic cavities. The illusion was heightened by the absence of the normal left dulness. But why the abnormal impulse? There could be no doubt about it, and its presence was noted by several observers.

Netley.

NOTE ON A CASE OF QUARTAN AGUE IN NEW ZEALAND.

BY ROBERT H. BAKEWELL, M.D. ST. AND. & N. Z., LATE PHYSICIAN TO THE CHRISTCHURCH HOSPITAL, NEW ZEALAND.

THE patient was a woman, aged about forty-five years, who lived near a swamp, but with a hill between her residence and the swamp. For the last month she had been subject to frequent attacks of chills followed by heat and perspiration. From one of these attacks she was suffering when I was called in on August 19th at 8 P.M. The temperature was 101·6° F. and the pulse was about 100. It appeared on close questioning that these attacks occurred every four days—that is, one, say, on the Monday, the next on the Thursday, always with two clear days. The attacks commenced about 4 P.M. and lasted until the morning; they were accompanied by some headache, great lassitude, aching of the limbs, and the other symptoms of intermittent fever. I ordered 5 gr. of sulphate of quinia *statim*. The dose was to be repeated at 8 A.M. On calling the next morning at 10 I found that she had taken both doses; there had been no singing in the ears, the temperature had fallen to 96°, and she was ordered 10 gr. of quinine daily for two days more. In all she took 30 gr. This sufficed to stop the quartan, of which there was no recurrence, and produced no cinchonism—a sure sign that it was needed. The rarity of quartan ague must be great, as I have never seen a case for forty-seven years when I resided on the borders of the Essex marshes.

ST. THOMAS'S HOSPITAL.

A CASE OF RUPTURED INTESTINE WITHOUT ABDOMINAL WOUND; LAPAROTOMY; DEATH NEARLY A MONTH LATER.

(Under the care of Mr. W. H. BATTLE.)

RUPTURE of the intestine without any wound of the abdominal wall is probably not very rare yet the number of cases which have been recorded is by no means great. The amount of damage exhibited by the skin of the abdomen is no criterion of the severity of the injury inflicted on the subjacent viscera. The skin may show only a slight abrasion and yet rupture of the liver or the intestine may have occurred. In cases like these, where the wheel of a cart has passed over the abdomen or a severe kick from a horse has been received in the same region, the diagnosis is exceedingly difficult. If the bowel has been ruptured by what signs can it be known? Unfortunately no very definite answer is possible to this question. The great amount and persistence of the collapse may suggest that an injury greater than a mere contusion has been inflicted but it cannot be said that reliance can be placed on this. It was formerly maintained, and the view is still held by many, that absence of liver dulness always occurs in rupture of the stomach or intestine and that the presence of this physical sign is pathognomonic of this condition, but neither of these statements is absolutely true; it *usually* happens that a rupture of the intestine or of the stomach allows sufficient gas to escape

Digitized by Google

to cause the liver to drop away from the abdominal parietes so that a resonant note is obtained, but it is not always so, and, on the other hand, a highly distended bowel may encroach on the liver dulness. Persistence of the vomiting is a sign of some value, but it cannot be relied on. The diagnosis being so difficult it is natural that the decision as to the treatment to be adopted should be difficult also. In deciding on the treatment in a case in which the abdomen has received a blow or some similar injury two points have to be considered; the first is, do the severity and persistence of the symptoms point to some lesion greater than mere contusion? and the second point which must be considered is the severity of the blow. If this has been really great, as the passage of a heavy waggon or the kick of a horse, the severity of the blow in itself may justify an exploratory laparotomy. It is, of course, possible to open the abdomen and then to find that it has been unnecessary, but if due care has been exercised this is better than to find at the post-mortem examination that a lesion was present which could have been readily remedied. It is difficult to obtain trustworthy statistics as to the relative mortality between cases operated on and those in which no operation was performed, but it has been said that when cases are treated by systematic exploration after all severe injuries the mortality is 66 per cent., but that with the expectant treatment a death-rate of 97 per cent. is obtained,[1] but these figures are of little value. The following case has many points of interest and so far as the wound of the intestine went the treatment adopted was successful, though death occurred nearly four weeks after the injury. Some interesting cases of ruptured bowel have been recorded by T. Bryant;[2] in several of these the signs were extremely slight. Hitchcock,[3] W. H. Battle,[4] and J. Croft[5] have all published cases. At the last reference will be found a table of fourteen cases which have been recorded.

A man, aged twenty-seven years, was admitted into St. Thomas's Hospital during the evening of April 4th, 1898, having been, while crossing Whitehall when intoxicated, knocked down by a two-wheeled van, one wheel passing over the abdomen apparently below the umbilicus to judge from the abrasions. He was taken first to a hospital where they did not admit him. On admission at St. Thomas's Hospital he could give no clear account of the accident, but complained of pain in the abdomen and he had a slight scalp wound. The urine was drawn off by a catheter and was found to be free from blood. The temperature was normal and the pulse was fairly good. At 12 midnight after admission he commenced to vomit a clear fluid which smelt strongly of alcohol; the vomiting continued until 9 A.M. on the 5th, when he began to complain of pain over the abdomen which appeared very sensitive to touch and very resistant. There was no loss of liver dulness and no increase of dulness was present anywhere over the abdomen. The temperature was 100·6° F. In the afternoon (about twenty hours after the accident) the patient was anæsthetised with ether and an incision 5 in. long was made in the middle line through the umbilicus, and a large quantity of semi-purulent fluid escaped. The small intestine was turned out and found to be covered with flakes of lymph which easily peeled off. About 12 in. from the ileo-cæcal valve the bowel wall was discovered to be torn through; the tear was longitudinal and about three-eighths of an inch in length and was complete, the mucous membrane protruding. The tear was closed by means of 8 Lembert sutures of silk. The peritoneum was irrigated with hot sterile water and an opening was then made through the abdominal wall just above the pubes and a glass drainage tube was inserted. The first abdominal incision was then closed with salmon-gut sutures and dressed with cyanide gauze. The next evening (the 6th) the wound was dressed and a little slightly turbid fluid was removed through the drainage-tube with a pipette. The vomiting had continued although the patient was under the influence of morphia. Feeding was carried out by nutrient enemata. On the 7th the pulse was better but the vomiting still continued. A drachm of magnesium sulphate every hour was ordered but it was returned almost immediately. His temperature had not been above 99° since the evening of the 6th. On the 8th the patient began to feel better, his pulse was 62 per minute, and the temperature was normal. The drainage-tube was removed and a plug was inserted. He had had a great deal of hiccough but the vomiting gradually ceased. No food was given by the mouth. By the 9th he had very much improved and all vomiting and hiccough had ceased. A soap-and-water enema acted well and the patient felt more comfortable. He was given some Benger's food by the mouth and also a little milk and brandy, and no vomiting ensued. On the 10th he complained of pain in his back, but it was considered to be due to lying in bed. The bowels acted well and he took milk diet readily. He continued to improve and on the 12th the stitches were removed, but on the 14th the wound gaped and some bowel protruded, so the intestine was carefully washed and returned and the wound was resutured. On the 19th the temperature rose to 101·6°, but it subsided when a boric fomentation was applied to the wound. On the 22nd the temperature began once more to be irregular, rising at night, and on the 25th it reached 102·4°. The patient complained of much pain on the right side of the chest and on examination dulness at the back was discovered downwards from the level of the spine of the scapula; the dulness was not absolute and there was loss of breath sounds and of vocal fremitus. On the 26th an aspirating needle was introduced into the right side of the thorax posteriorly but failed to find any fluid. On the 28th, as the physical signs had not improved and as the evening temperature on the 27th had reached 103·4°, the patient was anæsthetised with chloroform and Mr. Battle tried with a trocar and cannula to find fluid in the right side of the chest, but as none was obtained an incision was made midway between the ninth and tenth ribs starting from the line of the anterior axillary fold and going forwards for about 4 in. and the pleural cavity was opened and a finger was inserted but nothing except what appeared to be solid lung could be detected. The incision was therefore continued forward in the same line over the abdomen and the peritoneum was opened just beneath the edge of the liver. A finger was introduced and felt what seemed to be some very soft recent adhesions among the coils of intestines but nothing else could be detected although the right kidney was easily felt. Over the upper surface of the liver nothing was felt and the finger easily reached the right coronary ligament. When one finger was put into the pleura and another into the abdomen nothing but diaphragm intervened between them. The wounds were sewn up and dressed. The patient's condition did not improve; he vomited after taking any liquid, his breathing was at the rate of 40 per minute, and his pulse was 160. There was no distension of the abdomen. He continued to grow worse on the 29th and he gradually sank, dying at 7 A.M. on the 30th.

Necropsy.—At the post-mortem examination which was made by Dr. H. W. G. Mackenzie a small amount of serum was found in the right pleura. The lower lobe of the right lung was quite collapsed and portions of it sank in water. In the abdomen there were adhesions here and there between the intestinal coils, but these were readily broken down and there was no evidence of recent peritonitis beyond this. There was a collection of pus amounting to an ounce or so in the pocket of the peritoneal cavity behind the right lobe of the liver. This was very near the second incision made on the right side of the chest and the abdomen. It lay about an inch or so behind it. The site of the former rupture of the gut was in the small intestine about 12 in. from the ileo-cæcal valve. Several sutures were attached to the outer aspect of the gut and readily came away as if they simply adhered to the surface. The opening was quite closed. The other organs all appeared to be normal.

Remarks by Mr. BATTLE.—The result of treatment in this case of ruptured intestine was very disappointing to all concerned. The operation was performed as soon as it could be after I had seen the patient. The rent in the gut was found and satisfactorily closed, whilst the peritoneum was thoroughly washed and cleansed from adherent lymph. A mild infection of the abdominal wound probably took place at the time and although it appeared to be firmly healed when the stitches were removed some abrupt movement caused the union to give and prolapse of bowel followed as described. This in turn gave rise to a secondary infection of the peritoneum and to the subdiaphragmatic abscess for which exploration proved unsuccessful. The general state of the patient was very difficult to manage. The accident occurred when he was under the influence of alcohol and he was addicted to it; moreover, he

was of a headstrong disposition and impatient of control. On more than one occasion he got out of bed and it was only the skilful management of the house surgeon, Mr. John McClean, that carried him through the danger of the first four or five days. The difficulty attending the diagnosis of abdominal lesions directly after the infliction of the injury is again demonstrated by this case. All abdominal injuries should be admitted to hospital when they apply, and it cannot be too strongly emphasised that the most serious injury may be present without any apparent damage to the abdominal wall or any excessive shock. The diagnosis was very clear at the time I first saw the patient and I had no hesitation in preparing for immediate operation. In addition to the history of injury the abdominal pain was then very severe and the aspect of the patient indicated great anxiety. The vomiting which had been thought to have been possibly the result of drink continued and was frequent and distressing. Examination of the abdomen showed great rigidity of the abdominal wall and much tenderness. The percussion note was not impaired anywhere. As a rule there is, I should say, no dull area in cases of ruptured small intestine over the part affected by the injury unless there is associated with the ruptured gut a hæmorrhage from ruptured mesentery. If there were much contusion of the intestinal wall with hæmorrhage into it one could imagine some impairment of note, but it is not easy to understand how gut which has been paralysed by injury can produce a change in the percussion note sufficiently pronounced to be of use in the diagnosis of these lesions, though possibly this might be due to want of tone in the wall of the gut—compare the dull note obtained by slacking down a drum. French surgeons have expressed an opinion that it is little use operating for ruptured intestine if more than fifteen hours have passed since the injury, but it is to be hoped that this will not be accepted generally, otherwise we shall certainly lose cases which might have been saved. Dr. Wiggins successfully operated on a boy thirty-six hours after the injury.

ANCOATS HOSPITAL, MANCHESTER.

A CASE OF IRREDUCIBLE HERNIA; ADHESION OF INTESTINE, SEPARATION OF MESENTERY; RADICAL CURE; RECOVERY.

(Under the care of Mr. STANMORE BISHOP.)

THE special point of interest in the following case is the accidental separation of the mesentery from a portion of the small intestine. It is often stated that the bowel is liable to slough if this occurs and many instances of this serious result have been recorded,[1] but generally this happens only when the separation has been much more extensive than in the case recorded below.

A man, aged fifty-one years, was admitted into Ancoats Hospital on Jan. 10th, 1898. He was stout, flabby, and of rather coarse build; he had an irreducible scrotal hernia on the left side which he declared he had observed only for nine months; he had never worn a truss. After rest in bed for three days it became somewhat smaller but no attempt at reduction appeared to have any effect upon it. It was of about the size of a cricket ball and gave a clear note on percussion, apparently containing only intestine without any omentum. When the patient first noticed the swelling, about nine months before admission, it was of the size of a duck's egg, his attention being directed to it by some hypogastric pain. He had suffered from cough but he did not attribute the swelling to the coughing nor did he think it resulted from his employment, in which he had to lift heavy bags of coal. On Jan. 14th the operation for radical cure was performed. The veins of the spermatic cord were varicose, the cord itself being much thickened, elongated, and convoluted, but it was easily separable from the sac. On opening the latter a U-shaped coil of intestine was found; it was intimately adherent laterally; and while this adhesion was being separated by means of scissors it was found that the mesentery itself was being separated from the gut. The mistake was recognised almost immediately and the adhesions were then attacked nearer the neck of the sac and behind where a gap was found and from this point the work was easy. The bowel itself at the apex of the loop was shrunken and narrowed in calibre, looking indeed as though it had been compressed in the neck of the sac. At first resection of this portion was thought of, but the idea was rejected partly because the bowel retained its normal colour and gloss and partly because the patient showed signs of commencing collapse. The neck of the sac was divided upwards, the bowel was reduced, and the neck of the sac was tied, the remainder being cut away. The ring and canal were then sewn up by three mattress sutures, applied as Noble suggests, so as to draw the conjoined tendon behind Poupart's ligament, leaving only enough room for the passage of the cord. The wound was closed by horsehair sutures and sealed by celloidin. The patient was greatly collapsed on the same night and very sick, the vomiting lasting until the evening of the next day. The first motion was passed on the second day. Recovery was uneventful and the sutures were removed on the tenth day, the wound having healed by first intention. The patient was kept in bed for six weeks and left the hospital perfectly well on March 8th.

Remarks by Mr. STANMORE BISHOP.—This case indicates, I think, the amount of reliance which may be placed upon the anastomoses of vessels on the bowel wall, since in the process of separation several of the direct smaller supplying vessels were divided.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Lesions of the Pineal Body.

A MEETING of this society was held on Dec. 6th, the President, Dr. PAYNE, being in the chair.

Dr. CYRIL OGLE exhibited two cases of Tumour of the Pineal Body. The first was a pigmented mixed-celled sarcoma about 1½ in. in diameter associated with melanotic sarcoma diffused all over the cortex of the cerebrum and invading brain substance along the fine vessels. The appearance of the brain was as if it had been painted with dark sepia or black lead. Dr. Ogle referred to instances of diffuse sarcoma in the pia mater described by Ziegler and to a similar appearance due to melanotic sarcoma depicted in Bramwell's book on "Intracranial Tumours." The other specimen was a mass about 1 in. in diameter, limited to the region of the pineal body but pressing on and causing atrophy of part of the optic thalami and corpora quadrigemina, the rest of the brain, including the pituitary body, being healthy. On microscopic examination it proved to be of complex character, partly composed of vascular tissue like hyperplasia of the normal pineal body, but also of collections of exceedingly large cells with vacuolated nuclei and of cystic spaces lined by cubical epithelium. The whole, perhaps, was to be regarded as alveolar sarcoma or endothelioma, with a tendency to revert to structures found in birds in the pineal body. The symptoms in this case included rapid blindness with dilated inactive pupils, no paralysis of the third nerve, but loss of the external movement of each eye. There was no other paralysis or loss of sensation, but there were staggering gait and stiffness of the muscles of the back, vomiting, and fits, great enlargement of the penis and almost continuous sleep for from five to six weeks or longer. Dr. Ogle referred to 8 other cases of pineal tumour, 2 being hyperplasia or glioma, the remainder each of a complex constitution, some containing hair, cartilage, and fat, others containing spaces lined by epithelium suggesting glandular tissue, most of them containing cysts and sarcoma tissue. Dr. Ogle pointed out that the pineal body developed as a hollow outgrowth of the fore brain, elaborated as in certain lizards, as shown by Baldwin Spencer, into a median eye of very perfect elements, but in mammalia remaining in a rudimentary or rather a degenerate condition as a solid body containing compartments filled with reticulum and cells, processes of which appear to form the reticulum. It had been suggested that the body might have nervous functions, its appearance being somewhat like that of the granular layer of certain parts of grey matter of cerebrum or cerebellum, but the appearance was more like that of masses of neuroglia. Dr. Ogle then considered whether the body had any metabolic function comparable to that of the pituitary or thyroid bodies, although not representing, as they do probably,

Digitized by Google

glandular, secretory, or excretory structures in earlier types of animals. He considered that it was fair to conclude that the symptoms in the uncomplicated case of pineal growth could be well explained by pressure on the corpora quadrigemina, hence the rapid blindness without choked disc, stiffness, staggering gait, loss of conjugate movement of eyeballs. But possibly the precocious development of penis might have some relation to disease of the pineal in the same way as pituitary tumour appeared to cause enlargement of the extremities, although apparently this was not borne out by the scanty clinical details of other cases. In the same way the excessive sleepiness, with perfect intellect when aroused, might be an effect of pineal disease. This was found in several of the other cases collected and was not readily explained.

Mr. T. W. P. LAWRENCE exhibited a specimen of Glioma of the Pineal Body. The organ was slightly enlarged, circular in outline, and compressed from above downwards. It measured 14 mm. in diameter and 7 mm. in thickness, and showed slight signs of lobulation on its surface. Histologically the tumour consisted of a dense reticulum of delicate fibrils with scattered cells of small size, scanty protoplasm, and of round or triangular type. A large proportion of the tumour had undergone degeneration and consisted of granular material. The substance of the pineal body was disposed as a narrow zone at the periphery of the new growth and was divided up into distinct areas by the latter. The pineal body was free from adhesion to surrounding parts. The specimen was taken from a boy, aged sixteen years, who was under the care of Dr. Bradford at University College Hospital. The patient died from tuberculous meningitis of ten days' duration; his previous history was good and he had been free from illnesses, and there were no symptoms referable to the presence of the enlarged pineal body.

Mr. J. R. LUNN exhibited a specimen of Syphilitic Hypertrophy of the Pineal Body which was found post mortem in the brain of a demented female epileptic who had been in an asylum for ten years. She had had marked symptoms of acquired syphilis and ultimately died from tuberculosis. She had left hemiplegia and frequent fits, but owing to her mental condition accurate investigation of her symptoms was difficult. At the necropsy the pineal body was found greatly hypertrophied, it being affected with fibrosis evidently of a syphilitic nature. There were also two gummata in the brain, one in the tip of the left occipital lobe and the other in the right Rolandic region.

Dr. A. E. RUSSELL showed a Cyst of the Pineal Body found in the body of a man, aged twenty-three years, who was admitted into St. Thomas's Hospital comatose suffering from fracture of the base of the skull the result of an accident. The pineal body was found to be distended by a thin-walled cyst containing clear albuminous fluid. No other lesion was found. Careful inquiry from his friends failed to discover that he had shown any symptoms during life.

Mr. S. G. SHATTOCK showed an exactly similar cyst from the Museum of the Royal College of Surgeons of England. The history of the specimen was not known.

Dr. A. W. CAMPBELL (Rainhill) exhibited two specimens of Dilatation of the Central Canal of the Pineal Body. The first case was that of a female epileptic, aged thirty-three years, who died from phthisis. The only marked intracranial lesion was enlargement of the pineal body, 13 mm. in length, 10 mm. in width, and 8 mm. in depth, with a cyst-like dilatation of its central cavity, the contents being a glairy, brownish fluid. The wall of the cyst was composed of two layers; the outer was composed of normal pineal tissue, the inner stained indistinctly and contained several large, pale, or faintly granular cells, the nature of which was not evident. There were also scattered cells containing brown pigment. At the posterior part of the cyst these pigmented cells were arranged in a definite stratum. Possibly these might be hæmatoidin collections, but it was also possible that they were pigmented cells analogous to those found in the choroid and retina, and would confirm the view that the pineal body was a rudimentary organ of sight, and would also explain the origin of a primary melanotic sarcoma in that body. The second specimen was also taken from an epileptic female and was similar except that the dilatation was greater. Unfortunately no microscopic examination was made.

Dr. GARROD showed a specimen of Cyst of the Pineal Gland taken from the body of a boy, aged sixteen years, who died from diabetes. The necropsy was made thirty-five hours after death. The pineal body contained a small cyst cavity of the size of a pea with smooth walls. It contained no hæmatoidin crystals. The fourth ventricle appeared to be quite natural and no other cysts were found in the brain. The pancreas was small and was found on microscopic examination to be markedly fibrotic. The liver and kidneys were fatty. It was probable that the cyst was of the same nature as those shown by Dr. Russell and Dr. Campbell.

Dr. VOELCKER showed a specimen of a Pineal Body in which there was a calcareous deposit. There was a similar deposit in the choroid plexus on each side and extensive calcareous degeneration in the arterial walls. There were no symptoms during life pointing to an intracranial lesion.

The PRESIDENT remarked that the pathological importance of the organ was evidently small, as was to be expected from the fact that in the higher animals it seemed to be of a merely rudimentary character. As Dr. Ogle had pointed out, it was recognised as having been (far back in the scale) an eye, but that must date back to the time when the tissues were transparent. After opaque substances began to be deposited in the tissues a central eye would become useless unless brought up to the top of the head, as in certain reptiles. Cyst formation, such as had been illustrated, was characteristic of rudimentary bodies. The occurrence of pigment was interesting as in the early days of the organ there must normally have been pigment present. The cases quoted had shown that the symptoms were those of mechanical pressure on adjacent parts and did not at all suggest that the pineal body had any functions analogous to those of the pituitary body in forming sub stances which entered the blood.

ULSTER MEDICAL SOCIETY.

Ulceration following Scarlet Fever.—Laryngeal Diphtheria.—Classification of the Colon Group of Micro-organisms.

A MEETING of this society was held on Dec. 1st, Dr. NELSON, President, being in the chair.

Dr. T. S. KIRK showed a child with extensive Ulceration following Scarlet Fever and producing a curious deformity of one foot, the toes being covered by a fold of skin. A radiogram was exhibited of the deformity.

Dr. A. B. MITCHELL read a paper on the Influence of Antitoxin on the Mortality of Tracheotomy for Laryngeal Diphtheria, with special reference to the results of operation in Ulster. Attention was first drawn to the prevalence of diphtheria in the north of Ireland, this being illustrated by a mortality of 3402 from this disease in Ulster during the past twenty years, while during the same period in all the rest of Ireland the deaths from the same cause were only 3320. The annual death-rate per 100,000 in Belfast and the surrounding district was 14, while a similar rate for Dublin was only 7. The beneficial effect of antitoxin in the treatment of diphtheria and the consequent reduction in the mortality from this disease was referred to and it was then pointed out that the benefits to be derived from its use were still more striking in those cases where tracheotomy became necessary. The recovery rate after tracheotomy in the hospitals under the Metropolitan Asylums Board, which was 28 per cent. without antitoxin, had risen to 63 per cent. since the introduction of the serum. For years there had been a firm conviction in the minds of the profession in Ulster that tracheotomy in diphtheria offered no reasonable prospect of saving life and it was therefore only performed on rare occasions and, indeed, rarely recommended. Dr. Mitchell communicated with the leading surgeons throughout the province of Ulster and succeeded in collecting a series of 82 operations performed for this disease previously to the introduction of antitoxin. Of these only 6 recovered, equal to a recovery-rate of 7·3 per cent., a record sufficiently gloomy to justify the feeling of the profession in regard to it. A similar list since the introduction of antitoxin yielded a total of 20 operations with 15 recoveries, equal to a recovery-rate of 75 per cent. Though the number of cases was comparatively small it was contended that the figures were convincing and the attitude of the profession in the North of Ireland towards tracheotomy must be reconsidered. The value of artificial respiration after the trachea had been opened in those cases in which respiration had suddenly been suspended was particularly insisted upon, and records were

Digitized by Google

given of cases in which this measure had resulted in a restoration of vitality in what appeared to be a death-sleep. The value of intubation as compared with tracheotomy was discussed and the former operation was condemned in diphtheria: (1) as being likely to force any pieces of loose membrane down into the trachea with the risk of instant suffocation; (2) as giving rise to great difficulty in feeding; (3) as liable to cause ulceration of the swollen vocal cords with permanent impairment of function; (4) because it did not afford such free exit for pieces of membrane, tracheal secretion, &c.; and (5) if coughed up the nurse was totally unable to replace the tube. Finally, the necessity for prompt administration of antitoxin in all suspicious cases was urged, this being calculated greatly to diminish the number of cases likely to require operation at all.—The discussion was carried on by Professor SINCLAIR who thoroughly agreed with Dr. Mitchell in his opinion of the improved prospects of operation, in the value of artificial respiration in special cases, and in condemning intubation as unsatisfactory in the disease under consideration.—Dr. DARLING (Lurgan), Dr. CALWELL, Dr. KIRK, Dr. DEMPSEY, Dr. KILLEN, Dr. ROBERT CAMPBELL, Dr. TENNANT, and the PRESIDENT also took part in the interesting discussion.

Dr. J. LORRAIN SMITH and Dr. TENNANT made a communication on the Classification of the Colon Group of Micro-organisms.

BOMBAY MEDICAL UNION.—Three meetings were held during the month of November, to consider the present position of the Plague Prophylactic Inoculation of Professor W. M. Haffkine, under the presidency of the Hon. Dr. Bhatchunder Krishna. About fifty local medical men took part in the discussion. The following propositions and amendments were put before the meeting.—Proposed by the Hon. Dr. Bhatchunder Krishna and seconded by Mr. D. S. Shroff: "1. That this meeting is of opinion that, considering the data now available and the satisfactory results of the observations collected regarding the protective effect of Professor Haffkine's plague prophylactic, the time has now arrived for the profession to make a definite pronouncement on the subject and to invite the public to resort freely to the protective treatment, a very reliable safeguard against plague. 2. The immunity derived from inoculation when done with a full dose appears to last for at least six months, but there is the possibility of its lasting much longer. 3. From the observations collected it appears that a second inoculation done ten days or so after the first further reduces the incidence of plague in those who resort to inoculation, and a third, if such be practicable, would increase the immunity still further. The public are therefore to be invited to resort to at least two inoculations and even to a third if practicable. The duration of protection is also likely to be enhanced by such a repetition. 4. This meeting of medical men, who have had a wide experience of inoculation on persons of all positions, ages, and conditions, declares emphatically that rumours of inoculation originating different diseases, such as leprosy, syphilis, &c., are devoid of any foundation; that considering the nature of the prophylactic which does not contain any living germs such an eventuality is absolutely impossible; and that there are no facts to show that inoculation aggravates any existing ailments despite of rare and isolated instances which may at first suggest such an idea."—The following amendments were proposed by Dr. M. G. Deshmukh and seconded by Dr. G. B. Kher: "1. That in the absence of any series of experiments showing (*a*) that the apparently dead organisms contained in the prophylactic serum are incapable of growth in the bodies of animals as well as in men and (*b*) that the introduction of living germs of the disease in the inoculated animals does not only fail to produce any symptoms of the disease but that the germs do not at all grow there but are speedily destroyed—i.e., the immunity conferred on the animals is not only of the antitoxic kind but is powerfully anti-microbic—it is not possible to say that the general adoption of Professor Haffkine's anti-plague inoculation as a measure to combat plague epidemic is free from evil events. 2. In the absence of statistics of plague mortality among the inoculated and uninoculated sections of communities, giving full details regarding the age, sex, race, social position, and such other factors as confer natural immunity on individuals against a disease, no opinion can be expressed as to what degree of immunity is obtainable from inoculation."—Proposed by Dr. Nadershaw H. E. Sukhia and seconded by Dr. Khaja Abdule: "That in giving due and fair consideration to both sides of the question of the prophylactic effect of Professor Haffkine's anti-plague preparation, this meeting is of opinion that it is premature to pronounce definitely at this stage as to its harmlessness and efficacy or otherwise."—At the last meeting, held on Nov. 8th, on a division being taken, the amendments were thrown out, only 4 votes being given in their favour, whilst the original proposition was carried, the proposers and seconders of the two amendments alone voting against it. It was also resolved that the resolution passed by the meeting in favour of inoculation should be communicated to the public, the municipality, and the Government.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held in the society's rooms at the West London Hospital on Dec. 2nd, Dr. S. D. Clippingdale, President being in the chair.—Dr. J. B. Ball showed:—1. A case of "Black Tongue" in a girl, aged four years. The dark surface occupied an area in front of the circumvallate papillæ measuring about ¾ in. across and 1½ in. from before backwards, the anterior part and edges of the tongue being free. The characteristic hypertrophy of the filiform papillæ was well marked. The condition had been present for two months and had caused no trouble. 2. A case of Rheumatoid Arthritis in a boy, aged ten years. The disease had followed influenza two years previously with pains in the arms and legs and since that time there had been repeated attacks of pain and swelling of the joints together with fever. Certain joints now remained persistently enlarged between the attacks. The glands of the axillæ and groins were enlarged; there was no splenic enlargement.—The cases were discussed by Mr. McAdam Eccles, Dr. Bennett, and the President.—Dr. P. Abraham showed:—1. A case of Psoriasis in a girl, aged five years. The thumb became painful and the nail was lost a year ago; recently most of the other terminal phalanges had become affected. 2. A case of Lichen Ruber Acuminatus. The disease first appeared a year previously on the thighs, back, and abdomen. When the case was first seen in July, 1898, the rash had the appearance of a very red papular eczema. Pruritus had been a marked feature of the case.—These cases were discussed by Dr. Whitfield.—Dr. Alderson showed a case of recovery following Cirrhosis of the Liver. The patient had been tapped several times for ascites. Since the last tapping, more than a year previously, there had been no return of the ascites and the patient was able to do his work.—The case was discussed by Dr. Travers, Dr. Chapman, Dr. Caley, Mr. Bidwell, and Mr. McAdam Eccles.—Mr. McAdam Eccles showed:—1. A case of Submaxillary Cyst in a woman, aged thirty-nine years. The patient first noticed a swelling of the left submaxillary region two years previously. There had been no pain and the swelling had apparently remained of the same size. 2. A case of Swelling in the Region of the Parotid which had lasted for two years. There were no other swellings in the neck; the patient had several bad teeth.—These cases were discussed by Mr. R. Lloyd and Mr. Bidwell.—Mr. Keetley showed a case of Comminuted Fracture of the Olecranon which had been treated by wiring. At the time of the operation a considerable fragment of bone was found loose and had to be removed. Nevertheless the result was excellent and movement of the joint was practically unimpaired.—Observations on this case were made by Mr. McAdam Eccles.—Dr. Whitfield showed a case of Pityriasis Rubra in a man, aged forty-eight years. The disease had lasted for ten years.—Remarks were made on this case by Dr. Abraham.

ÆSCULAPIAN SOCIETY OF LONDON.—A meeting of this society was held on Dec. 2nd, the President, Mr. D. H. Goodsall, being in the chair. Mr. F. Hewitt Oliver showed:—1. A specimen of Extensive Necrosis of the Horizontal Rami of the Inferior Maxilla due to yellow phosphorus fumes from a man, aged twenty-eight years. The second bicuspid was absent and the third molar was carious on the left side. Suppuration extended from the cerebral base to the clavicle and was deeply burrowing. The spleen was large and soft and the other viscera were macroscopically healthy. 2. A specimen of Uterine Fibroids removed post mortem from a woman, aged eighty-seven years, of the size of three large fists, yet beyond their weight they produced no symptoms. Parts of the tumour were far advanced in calcareous degeneration.—Dr. Arthur Davies showed two cases of Myxœdema. One was a man who

Digitized by Google

had been under treatment since December, 1891, by thyroid extract, of which he takes now 0·3 gramme twice weekly. His condition is good and the alteration is very great. The other was a woman who had previously had a two years' course of thyroid treatment, but having left that off for nineteen months she had relapsed. Dr. Davies made some observations on the disease and treatment.—Mr. Reginald Brown read notes of a case of Acute Relapsing Idiopathic Neuralgia in a woman, aged thirty-five years, of no occupation, who after years of domestic anxiety developed pain in the teeth of the right superior maxilla in October, 1896, which soon extended to both sides of both jaws. All the teeth were removed with some benefit after drugs had failed. In October, 1897, the pain returned and was unrelieved by drugs so a neurectomy of the right inferior dental nerve was performed with relief from pain till February, 1898, when there was return in the left lower jaw and again drugs failed so neurectomy of the left inferior dental nerve was done when pain ceased for three months. In July pain began insidiously in the depth of the superior maxilla. Voltaic and Faradaic electricity was then used, which increased the pain. Weir-Mitchell treatment for six weeks failed to relieve the pain and weight was lost. Bromide and chloral hydrate taken nightly induced sleep for two or three hours only. Subsequently about 5 cm. of the infraorbital nerve had been removed. The case is still under treatment.—Dr. G. Denton showed a specimen of a Gall-bladder full of Gall-stones from a man, aged sixty-eight years, which gave rise to no symptoms.

KIDDERMINSTER MEDICAL SOCIETY.—A meeting of this society was held on Nov. 25th, Mr. E. H. Addenbrooke, President, being in the chair.—Mr. J. L. Stretton mentioned the case of a woman, aged forty years, upon whom he had performed Cæsarean Section. She was admitted in September with extensive malignant disease of the cervix and vagina and was at the time about six months pregnant. The operation was performed on Nov. 7th. She made an uneventful recovery and the infant, which weighed 4½ lb., is also doing well. It was remarkable that there was no suppuration in view of the extensive disease and the very fœtid vaginal discharge.—Mr. Stretton also showed a Rectum removed from a woman aged sixty-one years. She had suffered from symptoms for eight months and the operation was performed on July 12th. About 4 inches of bowel were removed and as the growth did not involve the sphincter the greater part of it was left and the bowel brought down and sutured to it. The bowels moved consciously on the eighth day. The stitches were removed on the twelfth day. On August 13th she was discharged cured. The bowels acted regularly and were under control. On Nov. 25th Mr. A. C. Oldham, who had charge of her, informed Mr. Stretton that she had full control of her motions. There was no contraction of the anus and no recurrence of the disease. This result demonstrates the advantage, in some cases at any rate, of suturing the bowel to the external sphincter.—Mr. Stretton also showed a man upon whom he had operated for Strangulated Hernia, read notes of a case of Strangulated Hernia in an aged female, and showed forty-two Gall-stones removed from a female patient. —Mr. Oliphant showed for Mr. Hodgson Moore a man from whose knee-joint a foreign body had been removed. It was a small piece of the articular surface, cartilage and bone, of the lower end of the femur which had been chipped off as the result of an accident. The man recovered without any bad symptoms and the joint is freely moveable.—Mr. W. Miles mentioned the case of a woman with a tumour in her side which resembled a moveable kidney, so much so that the surgeon who was consulted made an incision in the loin, but the tumour turned out to be a portion of the right lobe of the liver with a dilated gall-bladder attached.

ILFORD MEDICAL SOCIETY.—At a meeting of this society held on Dec. 1st Mr. P. J. Drought read a paper on the X Rays and gave several practical hints upon how to obtain the best results. He showed two excellent skiagrams which he had recently taken—one of a bullet in the wrist, the other of a bullet in the head. He was indebted to Mr. Stocker for having kindly placed these patients at his disposal and pointed out a difficulty encountered in producing the skiagram of the bullet in the head—viz., having seen a skiagram of this case in which the lead was not clearly defined, and which was also minus a nose, he brought his photographic knowledge into use and so placed the patient in a position which enabled him to view the bullet upon the screen; then moving the head slowly backwards and forwards in front of the focus tube he observed that the bullet which was lying beneath the malar bone became more sharply defined in some positions than in others, and, moreover, a fragment of lead which was embedded close to the temporo-maxillary articulation was at times visible and at times not, although the head had only been moved an inch at most backwards and forwards. In other words, he did exactly what the photographer does with his camera, he focussed the bullet and fragment upon the screen and having found the position which gave the results—i.e., showed both pieces of lead at the same time—he slipped the sensitised plate into the position previously held by the screen, fixed the patient's head, and so obtained an excellent skiagram, which in this particular case he could not have accomplished had he taken a haphazard skiagram of the head.—A vote of thanks, which was carried unanimously, terminated the meeting.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The third meeting of this society was held at the Royal Kent Dispensary, Greenwich-road, S.E., on Dec. 2nd, Dr. Morgan Dockrell, President, being in the chair. Several new members having been elected, Dr. A. E. Sansom delivered the Purvis Oration on "Some Practical Points in the Treatment of Heart Disease," which is printed in full on page 1536.—A vote of thanks to Dr. Sansom was proposed by the President, supported by Mr. Prior Purvis, and carried.—Afterwards a largely attended conversazione was held, over 70 members and guests being present.—Mr. Thomas Moore gave a practical demonstration on the working of the Roentgen rays, being assisted by Dr. Pepperdene and Mr. Ernest Payne, the former of whom also showed a Wydt-Rocheford coil.—Among the exhibits in the screen room were: Fracture of the Patella twenty-five years ago (upper fragment drawn up 8 inches; Fractured Arm; Rabbit in Bag; Bird in Cage; Ribs, Hands, Arms, Heart, Diaphragm, Legs, &c.—Mr. Cooper had charge of a room in which a number of beautiful Fluorescent Tubes, lent by Dr. Pepperdene, were exhibited. These included tubes showing many different fluorescing effects in varied vacua and others showing the spectra of the new gases helion and argon.—Mr. Leslie Miller lent an Apparatus for Demonstrating Wireless Telegraphy.—Over 200 Radiographs were exhibited by Mr. Moore, Mr. Poland, Mr. Payne, and Mr. Webster. — Mr. Ernest Clarke showed a number of interesting microscopic specimens and Messrs. Maw, Son, and Thompson gave an exhibition of Surgical Instruments and Appliances. — A feature of the decorations was a beautiful collection of Australian ferns, kindly lent for the occasion by Dr. Sansom.

Reviews and Notices of Books.

A Clinical Treatise on Diseases of the Breast. By A. MARMADUKE SHEILD, M.B. Cantab., F.R.C.S. Eng., Senior Assistant Surgeon and Lecturer on Practical Surgery to St. George's Hospital; late Assistant Surgeon, Aural Surgeon, and Lecturer on Operative Surgery to Charing-cross Hospital, &c. London: Macmillan and Co. 1898. 8vo. Pp. 510. Price 15*s.* net.

THERE are few parts of the body the diseases of which present more difficulties to the practitioner and the student than the breast and this is in great part due to the fact that the pathological aspect of many of the morbid conditions occurring in this organ has been allowed to overshadow the clinical, and therefore we welcome all the more gladly a work in which the clinical view of the diseases of the breast has been steadfastly kept to the fore, and though, as we shall see, the pathological problems which present themselves have not by any means been neglected, yet the diagnosis and treatment have been accorded distinctly the first place.

The material on which this work has been based has been drawn from Addenbrooke's Hospital, Cambridge, and other public institutions with which the author has been connected, but especially from a study of all the cases of disease of the breast which were admitted into

Digitized by Google

St. George's Hospital in the thirty years between 1865 and 1895. A valuable feature, which, however, may easily be carried to excess, is the inclusion of the notes of many illustrative cases. This adds much to the interest of the volume and cannot fail to impress upon the reader important clinical facts. The author while recording the views of others never hesitates to express his own opinion, especially in regard to treatment. The description of the development of the breast with which the volume commences is in a clinical work of necessity brief, but the chief points are touched upon. Creighton's opinion that the mamma is mesoblastic in origin nowadays receives no support, but of course this only applies to the secretory epithelium, and it is going too far to say that anyone claims that the mesoblast has no share in the development of the breast, for the fat, the vessels, and the fibrous tissue of the organ are indisputably mesoblastic. The histology of the breast is well described and is illustrated by four microscopic sections showing the structure at various ages and under different conditions. In the description of the mode of formation of milk the author says: "As the milk contains volatile substances and salts it can hardly be entirely formed by cellular disintegration but rather after the manner of sweat from the flattened cells on the walls of the acini." We must confess that we cannot see why volatile substances and salts should not be formed by cellular disintegration. Mr. Sheild has carefully looked for the cavernous tissue which has been described as existing in the nipple but he has been unable to find any trace of it, even after examining many specimens, and he ascribes the erection of the nipple under cold and mechanical stimuli to the contraction of the unstriped muscle fibres which are present. An interesting account of hypertrophy of the breast is given and it is pointed out that it is decidedly rare and that mistakes in diagnosis are often made. A girl with a very large breast was shown at the Fellowship examination of the Royal College of Surgeons of England a few years ago as an example of hypertrophy, but when the removal of the breast was attempted the enlargement was found to be due to a huge lobulated fibro-adenoma. One great point in the diagnosis of these cases is that in true hypertrophy the enlargement is nearly always bilateral. Elephantiasis also of the breast occurs and simulates hypertrophy and the author refers to several cases which have been recorded. In the treatment of hypertrophy Mr. Sheild urges that the milder measures, such as the recumbent position, elevation, and pressure, a dry and spare diet, with the administration of the iodides of potassium and sodium, should be given a fair trial before the surgeon resorts to amputation, and he quotes a very interesting case in which much benefit resulted from treatment on these lines. If we except malignant growths it may be said with truth that there is no disease of the breast of more importance than abscess, and for the whole account of this condition in this book we have nothing but praise. The author holds firmly to the view which is daily being more widely accepted that infection from the nipple is the sole exciting cause of mammary abscess and he tells us that he has never seen a case of acute mammary abscess in a young woman without having been able to observe, by the aid of a lens, breaches of surface in the vicinity of the nipple by which organisms might readily enter the lymphatic channels. Many of the cracks are so minute that without the use of a hand lens they will easily escape notice. The statistics collected show that after parturition abscess of the breast is most common between the fourth and eighth weeks and again towards the fifth month. The author says that abscess of the breast in connexion with lactation is largely preventable, and he bases his opinion on the results obtained in lying-in hospitals where, as he shows, care is taken to cleanse the nipple and the child's mouth, and cracks and fissures of the nipple are treated antiseptically. In the treatment of mammary abscess after it has formed Mr. Sheild holds that the ordinary anterior incision is seldom sufficient to ensure proper drainage and he advises a more thorough and elaborate method. "As soon as elasticity and deep fluctuation are evident an incision is made radiating from the nipple just large enough to admit the index finger of the operator, and this is deepened until pus flows. The finger is now passed into the cavity and in the vast majority of cases it will be found that the end of the digit may be brought fairly near the surface in a dependent position, and this is generally at the thoraco-mammary junction. In this situation it may especially be noted that scars are afterwards hidden from view." The breast being well raised a free opening is made, and in this way dependent drainage and a hidden scar are obtained. The anterior incision is carefully sutured with fine horsehair and painted with collodion, so that it leaves a very slight scar. We heartily agree with the author that for hæmorrhage after opening a mammary abscess no styptic can be worse than the perchloride of iron; turpentine is cleanly and efficient.

Chronic mastitis has always presented great difficulties in diagnosis and the directions given will prove of assistance in this matter. As to the treatment of this condition Mr. Sheild advises the persevering application of anodynes locally, with the internal administration of iron, arsenic, quinine, and general tonic remedies in those under thirty years of age, but for elderly patients in whom the disease resists pressure and mercurials he recommends the removal of the whole breast. The author looks upon Paget's disease of the nipple as a malignant papillary dermatitis and considers that it should be carefully distinguished from epithelioma of the nipple. He thinks, and we agree with him, that those cases in which recovery from a so-called Paget's disease has resulted from simple local applications were probably not cases of this disease at all, but examples of an ordinary eczema affecting the nipple and its neighbourhood. He hesitates to pronounce the peculiar bodies which can be seen in this condition to be psorosperms, but acknowledges that their presence is a sure proof that the case is one of Paget's disease. As to treatment, he advises that in all cases as soon as the diagnosis is certain the breast should be completely removed.

The study of tumours of the breast has been burdened by a most needless and extensive nomenclature, so that it is difficult to know what conditions the several terms denote. Mr. Sheild has wisely endeavoured to steer clear of these ambiguities and his classification is simple but sufficient. Putting aside the unimportant growths such as lipoma, chondroma, and osteoma, he divides the remainder into the three large groups of fibro-adenoma, sarcoma, and carcinoma. He rightly insists that both the pure fibroma and the pure adenoma are rare and that of non-malignant new growths the fibro-adenoma is certainly the most common. Statistics are quoted which conclusively show that the fibro-adenoma is much more frequently met with before forty years of age than after. Of 63 cases 45 occurred before forty years of age and 18 after. Recurrence may occur after the removal of a fibro-adenoma but the fresh tumours are to be looked upon not as examples of true recurrence but rather as due to the enlargement of smaller tumours which were already there.

True sarcomata of the breast are so rare that we need hardly say anything concerning Mr. Sheild's account of this disease except that we are glad to see that he mentions the possibility of a rise of temperature in cases of sarcoma. This fact is only too often forgotten. With regard to the lymphatic glands Mr. Sheild shows that they are by no means rarely affected in cases of sarcoma.

Two hundred pages are devoted to the subject of carcinoma of the breast and this is only in accordance with the importance of the subject. With regard to the relative frequency

Digitized by Google

of the disease in men and in women the statistics quoted show that it may fairly be said that 100 cases occur in females for every one that occurs in a male. The question of etiology is fully discussed and the author arrives at the conclusion that no certain statement can be made as to any connexion of carcinoma with parasitic microbes, but that there are certain indications in that direction. With regard to the results of modern treatment it is satisfactory to learn that there has been a distinct and steady decrease in the mortality after the operation of amputation of the breast. At St. George's Hospital in the "sixties" out of the first 100 cases 90 were operated on and 9 died from various septic causes; in the second 100, 88 were operated on and 4 died from septic diseases; in the third 100, 88 were operated on and 2 died, 1 from pneumonia and the other from erysipelas; and in the fourth 100, 97 cases were submitted to operation and 1 died from congestive pneumonia and another from sepsis.

We are pleased to see that Mr. Sheild advises that the operation of removal should not be performed with the knife which has been used to incise the tumour, for without laying too much stress on the evidence in favour of the parasitic origin of carcinoma, yet it is clearly undesirable to run any risk of infecting the healthy tissue through which the incisions for removal should pass. In all cases the author clears the axilla, and this is the usual modern practice even when no enlarged glands can be felt.

As to the final results it can hardly be said that cases are "cured," yet undoubtedly many patients survive the operation several years, and instances are quoted in which thirteen years have elapsed without recurrence. Mr. Sheild advises repeated operation in cases of recurrence unless secondary growths are manifest.

An appendix on diseases of the breast in the male concludes the volume.

The index is good and the employment of two varieties of type in it enables the reader to distinguish readily between the names of authors quoted and the diseases dealt with. The illustrations are excellent, both the coloured and the plain. The book may be confidently recommended to all who want a readable, trustworthy treatise on the diseases of the breast.

A Handbook of Hygiene and Sanitary Science. By GEORGE WILSON, M.A. Aberd., M.D., LL.D., F.R.S. Edin., D.P.H. Camb. Eighth edition. London: J. & A. Churchill. 1898. Price 12*s.* 6*d.*

THE fact that this work has reached an eighth edition is a sufficient indication of its popularity, and although since the book was first published numerous others, covering somewhat the same ground, have appeared, there has also developed amongst the profession and the public such a demand for books of this nature that a ready sale may safely be predicted for the eighth edition of "Wilson's Hygiene." The present edition has expanded considerably in bulk, much additional matter having been inserted and some sections entirely rewritten. For instance, in the chapter on Food a summary of milk-borne epidemics is given, and a discussion entered into as to bovine scarlet fever and diphtheria, while in relation to the filtration of water reference is made to the Massachusetts experiments and to Koch's work in the same direction. In the section on Sewage Treatment attention is devoted to recent biological methods without in any way encroaching on the description of the older systems of precipitation and filtration. The chapter on Infectious and Parasitic Diseases has been very materially expanded and the author's discussion of antirabic inoculation and serum therapy is calculated to make the readers of the work think out the whole matter for themselves. With the evidence as to the value of antirabic inoculation Dr. Wilson is far from satisfied, and although he seems to attach hardly sufficient importance to the value of control experiments in this connexion he furnishes some very plausible reasons for the views which he holds. The author is, too, by no means convinced as to the good effects of the antitoxin treatment of diphtheria; but we cannot say that we altogether follow his reasoning here, nor do we think that he attaches due importance to the remarkable results obtained in dealing by means of antitoxin with the extremely fatal form of this disease known as "post-scarlatinal diphtheria." Dr. Wilson is evidently inclined to the view that the deductions of the bacteriologists should be received with more scepticism by the profession, and he points to the enthusiasm with which the tuberculin treatment of phthisis was hailed as an illustration of what disappointment may follow from a too blind acceptance of the dicta of the bacteriologist. In the preface to the present edition the author observes: "From the point of view of practical sanitation I also venture to assert that the trend of microbial investigations has of late years threatened to ignore or minimise the influences of those conditions of environment without which many pathogenic organisms are powerless for mischief," and it is in this spirit that much of the chapter on micro-pathology is conceived. The section on Sanitary Laws and the Duties of Sanitary Officers is very comprehensive, including as it does the sanitary powers of county and parish councils, and the appendix contains useful memoranda and formulæ. Although the book is, by virtue of the multiplicity of subjects touched upon, of a somewhat impressionist character, a reader who peruses it with his critical faculty fully alive cannot fail to derive much useful information. But the student will do well to bear in mind that some of the views expressed in the chapter on Antirabic Vaccination and Serum-therapy are not those which find general acceptance amongst all pathologists at the present time. In some parts of the volume there is evidence of somewhat hasty revision, while in other parts it is not quite clear that the author has altogether assimilated some of the more modern reports to which he makes reference. The report made for the Royal Commission on Vaccination on small-pox in Gloucester is attributed not to Dr. Sidney Coupland, the author of it, but to Dr. Copeman, and the London Life Tables are put down to "Shirley," when obviously "Murphy" is intended. Other instances of hasty revision could easily be furnished, but in spite of this the book contains much valuable information and is a very readable and interesting production.

Diseases of the Heart and Aorta. By GEORGE ALEXANDER GIBSON, M.D., D.Sc., F.R.C.P., F.R.S. Edin., &c. Edinburgh and London: Young J. Pentland. 1898. Pp. 932. Price 24*s.*

IN the handsome volume before us the author has set himself the threefold task of presenting a faithful reflection of the science and art of medicine as bearing upon diseases of the heart and aorta at the close of the present century; while doing so, of making practical utility his chief aim; and, finally, of doing justice to authors whose name is Legion and a consultation of whose works has been necessary to the fulfilment of his purpose. It will be admitted that for the satisfactory accomplishment of so much special qualifications, qualities, and opportunities are necessary. The qualifications needed are a wide knowledge of the scientific principles underlying the physiology and pathology of disease and a practical instinct for applying these in diagnosis and treatment; the qualities required are inexhaustible patience, steadiness of purpose, and power of work; and the opportunities comprise direct access to extensive material, living, dead, and reported. Those who know the author's work and his position as a teacher in the Edinburgh School of Medicine can have little doubt of his fitness in these respects and we may at once state that

Digitized by Google

Dr. Gibson has in this volume shown himself to be possessed in an eminent degree of all the essentials for his task which we have indicated and that his work is, in our opinion, at once one of the most comprehensive, readable, and useful text-books with which we are acquainted. We shall now endeavour to justify the opinion which we have expressed.

The book consists of sixteen chapters, of which the first five deal chiefly with the scientific principles involved in the study and treatment of heart disease. In these morphology, physiology, pathology, semeiology, and therapeutic principles are lucidly discussed, and to the knowledge of some important points in these fields Dr. Gibson has contributed valuable material from personal observation and work. His interesting remarks upon the cardiac movements in a case of deficient sternum, upon rigidity of the arteries, upon venous pulsation, and upon Cheyne-Stokes respiration are well worthy of perusal. His exhaustive monograph on the last of these subjects is well known. In treating this theme he does full justice to the observations and opinions of others and thus renders his work, as was his intention, a concise and reliable reflex of current expert opinion.

The remaining eleven chapters deal in detail with the nature and treatment of diseases of the pericardium, the heart, and the aorta. Coupled with the indication of the conditions dealt with there is usually an interesting explanatory commentary when this is possible, and the chapters close with fully detailed clinical histories of illustrative cases which ought to prove very helpful to the student. It would be impossible within the space at our disposal in reviewing so encyclopædic a work to refer at length to many points of great interest, but in all sections of the book Dr. Gibson appears not only as the scholar but also as the personal observer, and he states his conclusions and the reasons upon which they are based in a clear and interesting manner. The normal and important physiological leakage in the right heart and the physical signs in so-called "weak heart" are fully considered. On the latter point the author agrees in the main with Russell in regarding the pulsation in the second left intercostal space as due to the movements of the conus arteriosus, and he has the frankness to disavow his previous adhesion to the view of Balfour that that sign is due to the pulsation of a distended left auricle. He regards the associated bruit to be indicative of tricuspid incompetency. This may be so, but the explanation of the bruit in the pulmonary area by propagation from the tricuspid orifice does not appear to us altogether satisfactory. We rather incline to the view expressed by several, that some cause of increased vibration in the blood-stream exists nearer the manifest seat of the sound. We agree, however, with the author that there are important objections to be urged against the specific explanations hitherto given. Again, in the matter of the serum-therapy of acute endocarditis, and without losing our confidence in the future results likely to accrue to science in this as in other departments from the preparation and use of these remedies, we feel disposed to remark that the author's satisfaction with the attained results in the cases indicated may not be shared by many others. With another recent or resuscitated development of cardiac therapeutics which is somewhat fully treated—namely, the gymnastic and balneological—Dr. Gibson deals in a very judicious manner and with an entire freedom from that unregulated enthusiasm which has done so much to discredit measures useful enough in their own place. It is of interest to learn that he has found the physical effects of the natural and artificial baths to be identical. The chapter on Complex Sensory and Motor Affections of the Heart, including angina pectoris, is an able and succinct account of a difficult subject. His pages on angina pectoris, indeed, contain within a comparatively short space a very complete account historically and clinically of an affection which for various reasons has had a fascination for medical writers and remind us in some respects of that classic, the memorable essay by Sir William Gairdner on the same subject in Reynolds's System of Medicine.

The last chapter deals with Diseases of the Aorta and includes an instructive account of the causes and nature of aortic aneurysm together with a well-weighed judgment upon the various methods of treatment which have from time to time been employed with an encouraging measure of success in some cases.

In a short Appendix on Roentgen Radiography the author notes the value of this method in determining change of position in the heart and the presence or absence of obscure aneurysmal and other intra-thoracic tumours, giving at the same time a good radiograph of displaced viscera. Of the illustrations throughout the volume it may be said that they are excellent and numerous and from the printer's and publisher's point of view the work leaves little to be desired. A copious and accurate bibliography which will be of great service to original workers and a good index terminate what may be looked on as one of the most complete of recent textbooks on diseases of the heart and aorta.

Mastoid Abscesses and their Treatment. By A. BROCA, M.D., Chirurgien des Hôpitaux de Paris, Professeur Agrégé à la Faculté de Médecine; and F. LUBET-BARBON, M.D., Ancien Interne des Hôpitaux de Paris. Translated and edited from the French by HENRY J. CURTIS, M.D., B.S. Lond., F.R.C.S. Eng., Assistant to the Professor of Pathology, University College; Assistant to the Ear and Throat Department, University College Hospital, London. With 11 Coloured Illustrations. London: H. K. Lewis. 1897. Crown 8vo. Pp. x. and 268. Price 6s.

MR. CURTIS has done well in introducing to English surgeons the valuable memoir by Broca and Lubet-Barbon, a work too little known in this country. It is difficult to over-estimate the importance of disease of the middle-ear. Its complications are so far-reaching and so dangerous to life that it is well worthy of more attentive study than is even now bestowed on it. Operations on the mastoid were performed long ago by Petit but they soon fell into disrepute, and it is only in recent years that the operation of opening the mastoid process has again become fairly frequent.

The dangers of the disease are great, but so also are the dangers of the operation which is intended to relieve it, and only a good knowledge of the anatomy of the parts concerned will enable the surgeon to escape the many pitfalls in his path. A brief but useful account is given of the anatomy of the mastoid process and its relations to the lateral sinus, the facial nerve and the brain, and the translator has very wisely inserted in the volume eleven coloured plates illustrating the anatomy of this region which have been taken from a paper by Mr. Rickman Godlee. These portray the relative positions of the structures as seen in sections made in various directions through the temporal bone, and a much clearer idea is gained by the examination of these diagrams than would be possible in any other way.

The work is divided into four chapters, the first of which is devoted to Mastoid Abscesses, the second to Mastoid Fistulæ, the third to Chronic Suppurative Inflammation of the Middle-ear in which the inflammation of the mastoid is latent, and the fourth chapter is concerned with the results which have been obtained.

The authors do not consider that as yet any classification of cases of mastoid abscess can be founded on bacteriological data, although many different micro-organisms are met with. Mixed infection is the rule but in one case they obtained a pure culture of bacillus coli. For opening the mastoid process a narrow chisel 5 millimetres (⅕th in.) wide at the most is recommended. The skin incision commences at the

Digitized by Google

apex of the mastoid, runs upwards to the level of the temporal line, and then turns backwards at a right angle and continues for about ¾ in. Thus is marked out a triangular flap which is raised from above downwards and backwards. The antrum is then opened by a square aperture corresponding fairly closely to the upper half of the mastoid process.

The statistics relating to the results after operations on the mastoid cannot fail to be of interest. 143 operations were performed on 128 patients for 133 diseased mastoid processes; 21 patients died, but in only 3 cases could the death reasonably be attributed to the operation; in 8 cases the fatal result was brought about by intercurrent maladies such as broncho-pneumonia and tuberculosis; 5 patients succumbed to intracranial complications which preceded the operation and 5 to sepsis which had manifested itself before any operative procedure was undertaken.

For the manner in which the translation has been performed we have nothing but praise; it is in clear, readable English and exhibits but slight traces of its French origin.

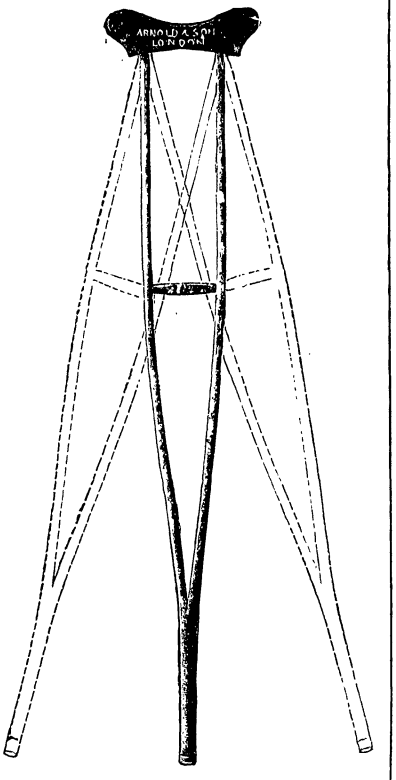
House Drainage Manual: a Guide to the Design and Construction of Systems of Drainage and Sewage Disposal from Houses. By W. M. SPINKS, C.E., President of the Institute of Sanitary Engineers, &c., Author of "Village Drainage," &c. London: Biggs and Co. 1898. Price 5*s*.

AMONG many good books written upon this important subject this book is one of the best. The author has succeeded in condensing with simplicity and clearness all the essential points to be observed in relation to the efficient drainage of a house, working upon the broad lines prescribed by the model by-laws issued by the Local Government Board. In only one or two places does he touch upon debatable ground—viz., where he advocates the entire disconnexion of the soil-pipes at their junction with the drain by means of a gully, the ends of the branch drains receiving these gullies having separate ventilating pipes. Whatever may be urged against this system it most certainly effectually cuts off all chance of sewer air entering the house through the soil-pipes and the pipes themselves have a better chance of being ventilated. On page 195, when dealing with country property he temporises with the cesspool, but inasmuch as he limits its capacity to the reception of one week's supply of sewage and provides that it is kept so far from the house as not to constitute a nuisance perhaps not much harm can accrue. Most of the well known defects common to badly constructed and badly planned systems of drainage are pointed out. Illustrations showing drain plans as suggested for various classes of property follow. In one or two instances we think a little additional ventilation should have been given to the branch drains to ensure the traps against syphonage. There is an excellent chapter upon Subsoil Drainage, a subject too much neglected. Then follows the consideration of the practical details, such as laying, inclination of, jointing, flushing, ventilating, and trapping drains, and a very detailed consideration of the many engines and appliances with which, unfortunately, our houses have to be surrounded. Their merits and defects are pointed out. Consideration is given to many of the methods in use for the ultimate disposal of sewage and a copy of the modern by-laws is added together with various Acts relating to public health. We can strongly recommend this manual to all who are interested in, or engaged upon, sanitary work.

CHRISTMAS BOOKS.

MESSRS. BLACKIE AND SON send us the following:—*Chips and Chops and Other Stories.* By R. Neish. Price 2*s*. This is a collection of pleasant little stories, the one giving its title to the book being about two dogs—a terrier and a bulldog. Some of the tales resemble those of Hans Andersen and are none the worse for that. The book will be an admirable present for children.—*A Mystery of the Pacific.* By Oliphant Smeaton. Price 5*s*. A story told by a Government inspector in the Polynesian labour trade. A "message from the sea" was picked up giving details of some castaways. When the Government schooner picked up this she started to find out the whereabouts of the castaways and finally discovered a mysterious island where dwelt the descendants of a colony of ancient Rome who had preserved all their forefathers' manners and customs. How the castaways were discovered and what adventures the rescuers met with must be sought in the pages of the book itself. A word of praise must be given to Mr. Wal Paget for his admirable illustrations.—*The Reign of the Princess Naska.* By Amelia Hutchinson Stirling. Price 2*s*. 6*d*. This is a very prettily written and pathetic little story about a child autocrat who ruled over a principality of apparently Russian nationality. The story is so well told and thought out that it was quite a shock to us to come to the following sentence uttered by the Princess's whipping boy, "Shucks! it would be as easy as—as crackers!" What the Tsarkovian vernacular for this would be we cannot say, but surely the author might have put the sentence in some other way. There is an error on page 114, where the Archbishop is spoken of as wearing a large "golden crucifix." This is something which no Oriental prelate ever does—i.e., if by crucifix is meant a sculptured figure. This error is reproduced in the illustration on page 131, but with this exception we have nothing but praise for Mr. Paul Hardy's drawings.—*At Aboukir and Acre: a Story of Napoleon's Invasion of Egypt.* By G. A. Henty. Price 5*s*. *Under Wellington's Command: a Tale of the Peninsular War.* By G. A. Henty. Price 6*s*. *Courage, True Hearts: the Story of Three Boys who sailed in search of Fortune.* By Gordon Stables, M.D., C.M. Edin., Surgeon R.N. Price 3*s*. 6*d*. Here are three Christmas volumes by two well-known authors which merit the attention of those who at the present season are pondering over the choice of a book or books for the amusement and edification of boys. The test which we apply to books of this kind is, we think, a practical and sound one—namely, to give them to some intelligent schoolboy for perusal and opinion. Judging from the avidity with which these volumes have been read they have certainly fulfilled their main purpose—that of interest and amusement. Self-respecting boys with wholesome instincts always have, and always will have, a keen appetite for deeds of daring and for stories of adventure and striking examples of prompt and decided action in safely getting out of "tight" places. These things set their imaginations aflame and later in life make them into soldiers, sailors, explorers, and colonists—not always to the entire satisfaction of their apprehensive mothers and staid fathers, but to the good of the nation notwithstanding. Two of the three volumes are from the prolific pen of Mr. G. A. Henty, who seems to possess an inexhaustible vein of good Christmas stories for boys. They deal with naval and military subjects. The first, "At Aboukir and Acre," is an opportune production at the present time when people's interest in Egypt has been keenly awakened by the exploits of Lord Kitchener of Khartoum and his expeditionary force in the Soudan and up the Nile. Napoleon's invasion of Egypt, the action in the Bay of Aboukir, and the defence of Acre by Sir Sidney Smith, make up a good and well-told narrative. "Under Wellington's Command," by the same author, is a tale of the Peninsular War, continued from Moore in Corunna up to the battle of Salamanca, and there is, as might be anticipated, no lack of incident. It is a sequel to one of Mr. Henty's books of last year and continues the adventures of a dashing Irishman, one Terence

Digitized by Google



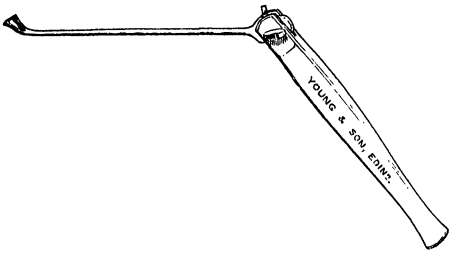
O'Connor, during the Peninsular war. Both books, it should be added, are capitally illustrated with plates and plans. Dr. Gordon Stables's volume, telling the story of three boys who sailed in search of fortune, is full of exciting situations and adventures and is likewise well illustrated. It is excellent reading for boys.

Messrs. C. ARTHUR PEARSON, Limited, have sent us the following:—*Strange Stories of the Hospitals.* By Frank Aubrey. Price 2*s.* 6*d.* This little book is published to be sold in aid of the metropolitan hospitals and medical charities. The author has presented it as a free gift to the Council of the Hospital Saturday Fund, who will receive all profits arising from the sale of the book and will apply them to the objects of the fund. This being so we will not attempt to criticise the stories further than to say that they are quite readable and will serve to enliven a spare half-hour. The expenses of publication have been borne by Lady Meux and Mr. Frank Isitt to whom as well as the author we offer our thanks for the assistance thus given to that form of charity in which we ourselves take a special interest.

New Inventions.

IMPROVEMENTS IN CRUTCHES.

WE have received from Messrs. Arnold and Sons, of West Smithfield, a pair of crutches of a new design, their distinguishing feature being that the padded leather-covered heads are not fixed immoveably to the uprights, but are capable of a limited rocking motion, so that as the person using them walks along the unavoidable to-and-fro movement of the crutch does not cause the head to shift its position in the armpits. A uniform pressure under the arm is thereby given and friction against the armpit is reduced to a very small amount, adding to the comfort of the user and diminishing the tendency to wear out the sleeve of the coat or dress. The crutches are strong and quite rigid in respect of affording support to the body, and at the same time the heads possess a certain amount of elasticity and "give" which will be appreciated by users. They have a well-finished appearance,



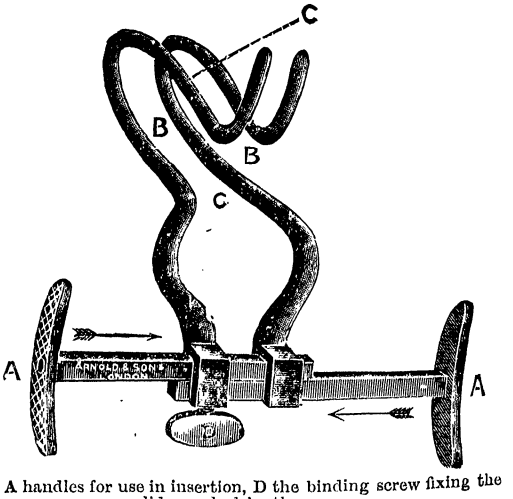
are light in weight, and are extremely simple in construction, having no springs or mechanism liable to become disordered. Messrs. Arnold and Sons state that a pair of these crutches have been recently tested by a cripple who walked 100 miles with them in one week without suffering from soreness or strain or otherwise distressing himself.

MILNE'S RIBBON GAUZE.

EVERY surgeon must have experienced great difficulty in using strips of gauze for plugging wounds; the gauze cannot be torn and must be cut to form a strip and then the edges are very prone to fray, so that particles of cotton can very easily be left in the wound. Mr. Charles Stonham has suggested the use of specially woven ribbon gauze with an edge which cannot fray, and the Galen Manufacturing Company, of Ladywell, London, S.E., have manufactured gauze of a uniform width of 2 in.; this is supplied either plain or medicated with the antiseptics in ordinary use, such as sal alembroth, carbolic acid, and iodoform. From a sample with which we have been supplied we are able to say that this ribbon gauze will prove useful for the purpose for which it is intended; it cannot fray as the threads of the woof do not terminate at the edge of the material. It is packed in bottles in convenient lengths of about 12 in.

NASAL CURETTES.

THESE instruments, of which an illustration is given, have been designed for the purpose of performing curettement of the nasal mucous membrane. Each curette consists of a handle and a blade jointed together in such a way as to permit of its being flexed to, and fixed at, any angle that



the operator may desire. The curettes, of which there are five in a set, vary according to the size, shape, and angle of their scraping points. They have been made for me by Messrs. Young and Son, Forrest-road, Edinburgh.

Edinburgh. G. HUNTER MACKENZIE, M.D. Edin.

A NEW PARALLEL EXPANDING RECTAL SPECULUM.

IT is said that the multiplicity of instruments for one use indicates that not one is perfect. If this be so no excuse is needed for invention or improvement. After a fair trial of the instrument represented below—which has been skilfully made by Messrs. Arnold and Sons at my suggestion—I can confidently recommend it. It is simple, effective, and self-retaining. Its open construction affords an extensive field, allowing

A A handles for use in insertion, D the binding screw fixing the slide marked by the arrows.

of many manipulations. Thus C C and B B are open spaces. To open the instrument the hand grasps and approximates A and A, or with obdurate sphincters the thumb may be placed in C, and C and A approximated. Thus the resistance of the sphincter is met by the intelligent hand and not by a lever or screw. The instrument is shown partly open. To withdraw see that D is not in action and press the blades together.

Finsbury-pavement, E.C. JAMES MACMUNN

Digitized by Google

THE LANCET.

LONDON: SATURDAY, DECEMBER 10, 1898.

WE are disposed, upon consideration of the various penal cases decided upon by the General Medical Council at their recent sitting, to be very proud of our profession. A great deal is heard about any irregularity of conduct in a medical man when it occurs, but that is because the general standard of behaviour is so high that all departures from it excite comment and surprise. *Noblesse oblige:* the obligations of our high functions are recognised and they are fulfilled. Upon what other view can we explain the fact of the small list even of charges which are brought against members of the profession for professional misconduct and the comparatively light nature of the charges themselves? The public despite the strenuous attempts of a section of the lay press trust their medical men, and they may well be confirmed in their high estimate when they see that of 34,000 men only 5 have been brought under the disciplinary notice of the General Medical Council and that but 2 of these were found to have been unworthy to remain on the Medical Register. We are no apologists for any laxness of professional behaviour, for any falling away from the high standard of service which the best practitioners have set up for their own guidance and which the man whose work lies among the poorest of our inhabitants or in the remotest village of our land often best exemplifies. But the tribunal of the General Medical Council is not a lax one, and when we look at the penal cases recently heard before it we feel almost inclined boastfully to aver that the natural liability of human nature to error is in the medical profession reduced to a minimum. We recommend our readers occasionally to devote a few moments to the consideration of cases which come before the Council and which, of course, represent a larger number of similar cases which evade such publicity. The study of them will help practitioners to avoid those technical offences which are apt to involve a summons to appear before the General Medical Council.

In 2 only of the 5 cases brought under the judicial notice of the Council did the Council proceed to the use of its great and only weapon of punishment—the removal of the offending practitioner from the Medical Register. One of these was the case of JOHN LLOYD WHITMARSH. The Council in his case was spared the trouble and the pain of an investigation of the facts which do not need any repetition here. His conviction at the Central Criminal Court for the murder of ALICE BAYLY being duly reported to the Council its duty, under the 29th clause, was obvious. His removal from the Register purges the profession of one who had brought disgrace on it. The use of medical knowledge to commit illegal and immoral acts is the greatest prostitution of knowledge. The public has great reason to be pleased when this crime is brought to light and when condign punishment falls on the offender, but it cannot be more gratified by such exposure than are the members of the medical profession who feel that the preservation of human life in all its stages is their supreme function. The second and only other case of erasure was that of the name of Mr. FREDERICK ALFRED FISHER, M.R.C.S. Eng., L.S.A. This practitioner was charged with seeking to attract practice by public advertisements in newspapers of his dispensary for "nervous debility" in all the forms which that term suggests. We deeply regret that any registered practitioner should resort to such methods of attracting attention to himself and his remedies. The lesson to be drawn from Mr. FISHER'S fate is to avoid tampering with the weaknesses and ignorance of human nature and with all forms of practice which involve doing so. We desire to offer to Dr. HUGH WOODS our congratulations upon the effective way in which he conducted this very proper prosecution on behalf of the Incorporated Practitioners' Society.

The remaining cases which occupied much of the time of the Council are such as almost necessarily arise out of the system so lately prevalent of employing unqualified assistants and the resolutions of the Council restraining that practice. Three registered medical men found themselves on their defence before the Council for the alleged wrongful use of assistants in practice. They were all subjected to a long process of inquiry. In the end they were all told that the charge against them was not proved. In one case, that of Mr. CHARLES ALEXANDER DUCKET, the defendant was the qualified assistant of a registered practitioner and had been blamed at two inquests for sending an unqualified practitioner to help him in his principal's practice. In another case, Mr. FREDERIC MERCER was charged with sending an unqualified assistant in an emergency to a midwifery case, he himself having seen the case both before and after confinement. The third case, and in some sense the most interesting of the group, was that of Dr. JAMES HAVARD JONES, who stepped into the vacancy occasioned by the resignation of certain medical appointments at mines by Dr. JOHN JONES of Clydach, Swansea. Dr. JONES resigned after dismissing an unqualified assistant, Mr. GEORGE JENKINS, who had been for almost a generation a continuous element in the medical attendance on the miners of the district. Principals might change, but Mr. GEORGE JENKINS remained till the new rules of the General Medical Council came into force, when Dr. JOHN JONES, out of proper deference to the Council's authority, resolved absolutely to part company with him. But as a consequence he found himself forced to resign his appointments at the mines. Dr. HAVARD JONES, a stranger in the district of Clydach, found means at once of conciliating the miners and discontinuing the services of Mr. GEORGE JENKINS. He became Mr. JENKINS'S tenant, lived in his house, drove his trap, and paid his daughter for board. The evidence of "covering" was certainly weak, for there was no proof that Mr. JENKINS attended any cases with or for his tenant who was ably defended by Mr. LAWSON WALTON, Q.C.

The least pleasant but by no means the least useful part of the work of the General Medical Council is that which has reference to the penal cases. We are sure

Digitized by Google

that most of the members would be thankful if the cases which come before them could be dealt with by the individual bodies whence the degrees and diplomas of the accused persons have been obtained. It is certain that many of the offences for which members of the profession are brought before the Council would never become matters for public discussion if the bodies, whether universities or corporations, displayed a little more interest in their past students and gave them now and again a word of remonstrance in regard to behaviour which tends to place the practitioner in a discreditable light before the public.

WE have seen a printed memorandum from the Seamen's Hospital Society purporting to answer "paragraphs and letters" which have appeared "in the newspapers both lay and medical." Certain objections which have been taken to the scheme as at present promulgated are instanced and dealt with. The first objection mentioned is "that the selection of the Branch Seamen's Hospital was not a wise one and that the *Dreadnought* at Greenwich and Netley offered superior advantages." We have argued that neither the parent hospital at Greenwich nor the Branch Hospital is suitable for the proposed school and have stated the reasons on which we base our opinion. One of the main objects of the new school is to afford opportunities for candidates for colonial appointments to study tropical diseases and we believe that Netley, with its staff of teachers who have practical experience of tropical diseases and its admirably equipped bacteriological laboratory, together with the number of patients recently returned from tropical countries, would afford every facility for the purpose. Building, equipping, and maintaining at an enormous cost a new school at the Royal Albert Dock would simply be to duplicate what already exists and if the public were duly informed of these circumstances we very much doubt if the necessary funds would be forthcoming. The memorandum goes on to say, "There is no reason to suppose that the War Office would allow medical men of every class [i.e., civilians, medical missionaries, &c.] to study at Netley." We may reply that "civilians, medical missionaries, &c.," can, if they so desire, obtain ample instruction at the various medical schools and laboratories already in existence, whilst we believe that an arrangement might well be made between the Colonial Office and the War Office whereby the colonial medical officers might undergo a course of instruction at Netley.

The policy of the committee of the London School of Tropical Medicine is certainly curious, for in reply to the objection "that the concentration of tropical cases at the Branch Hospital will operate to the detriment of the parent hospital—the *Dreadnought*," they simply remark, "Concentration of cases of tropical disease at the Branch Hospital is certainly desirable, but patients suffering from tropical diseases and applying for admission to the *Dreadnought* Hospital would still be admitted and treated there." This practically admits the intention to deplete the *Dreadnought* Hospital of cases of tropical disease. The third objection selected for answer is the all-important one—namely, "that the clinical material offered at the Branch Hospital is insufficient and that the hospital is difficult of access." We have already given statistics, derived from the printed report of the Seamen's Hospital Society, which conclusively prove that the material of both the parent and the branch hospitals is not sufficient to justify the proposal to expend large sums on new buildings for the purpose of establishing a school. The total number of beds is to be only 45, whilst at Netley there are 1000. The memorandum states that the number of cases of tropical diseases under treatment at the Branch Hospital during the year ended Nov. 30th last was 81 (our figures were taken from the report 1895–96), and that of this total 31 were suffering from malaria; and then come the words, "These cases alone are sufficient to justify the establishment of a school there." Are they? All connected with general hospitals know that numerous cases of malaria, amply sufficient for instruction and investigation, are treated every year in the wards of such hospitals without the incurring of any special public expenditure.

The fourth objection attacked by the memorandum is "that it is unnecessary to build laboratories as it is proposed, seeing that at many places in London there are now fully-equipped establishments." The only answer offered is, "Every teacher of clinical medicine must be fully aware that to separate the laboratory from the ward is highly prejudicial to successful work." We very much doubt whether "every teacher of clinical medicine" would agree with this. A microscope with a few simple reagents might be kept in a room near the ward, but the laboratory, every clinical teacher would think, is better some distance away. The most complete reply on this point, however, is contained in a letter which we publish from Professor CROOKSHANK whose prolonged experience in bacteriological research gives to his opinion an authority which it would be difficult to dispute. We would especially draw attention to the last three paragraphs of his letter where a scheme is formulated which well deserves the attention of the Home Office. Professor CROOKSHANK'S communication strongly supports our view that new bacteriological laboratories are unnecessary. Finally in the memorandum the personal element is introduced. For this portion of the controversy there can be no doubt that the committee of the Seamen's Hospital Society is to blame. The letters published last week as well as those in our present issue show that an apology from the committee to the honorary staff of the *Dreadnought* Hospital is the least amend which can be made.

It is much to be regretted that the Royal College of Physicians of London was not approached in the first instance and asked to advise as to the foundation of the school. Looking to the manner in which the scheme has been introduced we cannot but feel that if every portion of it is managed in the same way as the attempted formation of the teaching staff has been, the Managing Committee will at once lose the confidence of both the medical profession and the public.

THE report of the Pharmacopœia Committee to the General Medical Council is well worth the serious consideration of the medical profession, since it foreshadows very clearly some of the steps which are to be adopted in preparing for the next issue of the British Pharmacopœia. It used to be

Digitized by Google

currently believed that in the intervals between the publication of the different issues the Pharmacopœia Committee sat with folded hands, placidly watching the sales of the volume, ordering new copies to be struck off as the supply showed signs of exhaustion, and waiting patiently until pressure of public opinion forced forward the preparations for a new Pharmacopœia. Whether this belief had any foundation in the past it is not our present purpose to inquire. The volume certainly occasionally became antiquated and its vitality was not completely restored even by the publication of an Addendum. This expedient could not be trusted to keep it abreast of the times, since though it was possible to give official recognition to new drugs and to give formulæ for new official preparations it was not possible to alter the existing Pharmacopœia without creating confusion and the only way to satisfactorily make any material change in the volume consisted in the publication of slips of corrigenda.

With the progress of knowledge, however, changes in the official standard are frequently necessitated and in the past the need of revision has found expression both from medical men and from pharmacists. The former have desired the recognition of newer remedies which, being found to be serviceable, should have their properties clearly defined so that the profession could rely upon obtaining a supply of definite composition and constant strength. Pharmacists, on the other hand, have been no less persistent in pointing out possible improvements in the modes of compounding the official preparations. It is obviously useless for any Pharmacopœia to retain instructions which have become obsolete, while it is equally futile for the volume to be overburdened with drugs which have fallen into disuse. Alterations, therefore, in any Pharmacopœia concern both pharmacists and members of the medical profession, and there has been a time-honoured dispute with regard to the legalised production of the Pharmacopœia under the auspices of the General Medical Council alone.

It is well known that in the preparation of the Pharmacopœia of 1898 very material assistance was afforded by the Committee of the Pharmaceutical Society of Great Britain, but, notwithstanding the value of the help which they afforded, the pharmacists of Ireland seem to have taken exception to their exclusion which was doubtless unintentional. It is interesting, therefore, to note the suggestion in the report of the Pharmacopœia Committee that the "Pharmaceutical Societies," a term which includes the Society of Great Britain and that of Ireland, should be invited by the Council to coöperate in the work connected with the publication of the next Pharmacopœia, and it will further perhaps tend to greater cordiality of work when it is realised that these societies may be invited to appoint representatives to confer with members of the Pharmacopœia Committee. In presenting the report Dr. LEECH said that instead of the Pharmacopœia Committee of the General Medical Council and the representatives appointed by the Pharmaceutical Societies working on independent lines, with Dr. ATTFIELD reporting from the one to the other, they would have in future a joint conference.

Another indication of the desire to improve the Pharmacopœia lies in the suggestion that, apart from the report on the criticisms passed on the Pharmacopœia to be prepared by Dr. ATTFIELD, some of these criticisms are in all probability to be investigated and reported on by experts in pharmacy and pharmaceutical chemistry. It will be remembered that the General Medical Council appointed referees who assisted in producing the Pharmacopœia of 1898, but it is now apparently the intention of the committee to be at work continuously accumulating information for the next publication of the Pharmacopœia. That the requirements of the medical profession are to be kept well in view is shown by the fact that Dr. TIRARD, who rendered such efficient service in connexion with the present Pharmacopœia, has been requested to act as reporter to the Pharmacopœia Committee on advances in pharmacology and therapeutics bearing on the Pharmacopœia. It is further to be noted that this committee has now been entrusted with the power to appoint experts in Pharmacy and Pharmaceutical Chemistry to report upon any matters which in the future may be deemed worthy of investigation.

Evidently, notwithstanding the amount of care which was expended in the production of the present Pharmacopœia, and notwithstanding its favourable reception and the notable absence of gross errors, the committee are clearly of opinion that some of the criticisms deserve notice which will involve further research before determining whether the criticisms are well founded. It is obviously the intention to proceed immediately with the accumulation of information and to leave no stone unturned that will enable those responsible for the next issue to produce an even more satisfactory result. As the law stands at present the Pharmacopœia must be issued under the authority of the General Medical Council, but this does not preclude a *rapprochement* which will permit the interchange of views between the pharmacists and the Pharmacopœia Committee.

THE question of the fees to be paid to public vaccinators for their work under the new Act naturally continues to be debated with interest by those who are primarily concerned. In particular, proposals as to fees for mileage have been largely discussed, as, for example, at the meeting of public vaccinators at Malton, of which a report appeared in THE LANCET of Dec. 3rd, and by the board of guardians of the Bootle Union, Cumberland, whose decisions were reported in a letter[1] by Mr. P. BUTLER STONEY, the public vaccinator of one of the districts of the union, while a short account of the meeting will be found at page 1574. At the Malton meeting, as reported, it was freely stated that some system of payment by mileage was the only fair one. In the end this opinion seems to have been to some extent departed from, as the unanimous resolution was "that the fees of public vaccinators should be 2*s*. 6*d*. and 5*s*. in urban districts and 2*s*. 6*d*. and 10*s*. 6*d*. in the rural districts, these fees to cover all duties." This would not be a system of mileage, though the terms of the resolution take general cognisance of distance. Mr. STONEY in his letter states that the public vaccinators of his union had, previously to their meeting with the guardians, determined to ask a travelling allowance of 1*s*. per mile for distances

[1] THE LANCET, Dec. 3rd, 1898, p. 1505.

Digitized by Google

over one mile whether the child visited were vaccinated or not at the visit. The result, however, was an arrangement which in principle follows the lines ultimately approved of by the meeting of public vaccinators at Malton. The guardians concluded that they would not pay for mileage, but that in the urban part of the district (an area of 1311 acres) the minimum fees would be given, while in the rural part (extending about five miles in one direction and eight miles in another) the payment for successful vaccinations would be 11*s.*, and for a small outlying portion about from twelve to twenty miles from the vaccinator's house 25*s.* Another of the public vaccinators of this union, with a district of about twelve miles, has had his fees fixed at 12*s.* 6*d.* per successful case, and still another, with an eight mile district, is to receive 9*s.* 6*d.* per case, the initial fee of 1*s.* being extra in all cases.

The reasons given by the Bootle guardians for refusing a mileage rate were that the Local Government Board would not allow such an arrangement and that there would be much difficulty in checking mileages and that this difficulty would give rise to disputes. It does not appear from Mr. STONEY'S letter whether the guardians had actually ascertained from the Local Government Board that they would not sanction a mileage rate (and that is a point to which we have referred in previous articles), but we do think some weight attaches to the other objection raised by the clerk—namely, the difficulty in checking mileage and the possibility of disputes. Perhaps since the discussion began too much has been made of this particular method of regulating fees by mileage and the Malton meeting may have been well advised in arriving at a resolution in the more general terms above quoted. Medical men hold many offices where distance is a factor bound to be considered as regards remuneration, yet they do not always or often have an exact scale of payment per mile. In club practice, for example, a common rule is that the medical officer's work shall be limited to a three-mile radius and that within that area there shall be no variation in the payment per member. In mining districts similarly many appointments take no note of distance as between one contributor and another, all the employés paying the same fee. Of course, in some places, especially in the case of clubs, the fee may be too low, but the remedy is not usually found in distinguishing between one distance and another but rather in having the fee increased for all members independently of distance. There seems no good reason why, within proper limits, a similar system should not prevail for public vaccinatorships—such a system, for example, as Mr. STONEY describes, in which, within the bounds of specified areas, the fees are alike, though they vary as between one area and another. Mr. STONEY asks our opinion of the terms obtained in his union and the only criticism we would make is with regard not to the payment for successful vaccinations but to the initial payment, or, as he calls it, the registration fee. This fee his guardians seem to have refused to raise above the minimum of 1*s.*, no matter what the distance may be. Whether or not this will result in much hardship must depend to a great extent on local circumstances. Assuming that anti-vaccination has little sway in his neighbourhood the cases in which a visit will not result in a vaccination should be comparatively few, especially in the more sparsely populated areas where infectious disease is less likely to prevail or to be a reasonable cause of postponement of vaccination. Yet the Bootle guardians seem to have been hardly logical. For if in one part of their district it is reasonable to increase the fee for successful vaccinations from 5*s.* to 25*s.*, it is difficult to see why some addition ought not also to have been made to the minimum fee for statutory visits. It is no doubt possible, however, that in fixing the payments for successful vaccination consideration may have been given to the fact that only the minimum payment was to be made for the initial visit even though it should not result in a vaccination. The opinion of the public vaccinators at the Malton meeting appears to have been that under no circumstances should the initial fee be less than 2*s.* 6*d.*, though they do not object to the minimum of 5*s.* for successful vaccination in urban districts. At the same time they resolved that in rural districts the fee for successful vaccination should be 10*s.* 6*d.*, but they did not propose any addition to the 2*s.* 6*d.* fee as suggested by them for the statutory visits in urban districts. It is not quite clear why in this respect they make no difference between urban and rural districts.

The Local Government Board in fixing the minimum fees at 1*s.* and 5*s.* had probably in view the case of a thickly populated district of small area with the vaccinator living and practising in the midst of it and with anti-vaccination at a low ebb or with the conscience clause so used as to exclude practically all objectors from the lists submitted by the vaccination officer. Looking to the considerable increase in expenditure which will be involved even in the minimum fees and to the noisy opposition to vaccination which exists in so many parts of the country the central authority seem to us to deserve the thanks of the vaccination service for supplying its members with so good a foundation on which to base their negotiations with their local boards. The Birmingham guardians, it may be noted, think the minimum scale too high. To demand a silk gown in the hope of getting a sleeve is a good working principle in many mundane affairs, and the resolutions arrived at by meetings of public vaccinators do not necessarily mean any want of appreciation of the action of the Whitehall Board. The result of the Nantwich appeal to the Board [2] will be awaited with interest. Mr. THOMSON, one of the public vaccinators there, pointed out to the guardians that the distance of the districts from the residence of the vaccinators in the union averaged from four to six miles. This is surely a case in which the minimum payments are insufficient and yet by a majority of 15 to 10 it was determined to pay no more, the consequence being that the matter will now be brought before the Local Government Board; and the case will be of much importance as indicating the views of the Board with regard to the operation of their minimum scale. It is satisfactory that boards of guardians are in many places taking up a more reasonable attitude than at Nantwich. At Malton and Norton (Yorkshire), for example, the fees, inclusive of all claims, are likely to be not less than

2 THE LANCET, Dec. 3rd, 1898, p. 1501.

Digitized by Google

2s. and 10s. instead of 1s. and 5s., and they are fixed at 2s. 6d. and 7s. 6d. in several metropolitan unions.

We learn, on inquiry, that a communication is about to be addressed from Whitehall to the boards of guardians in England and Wales on the matter of fees both to public vaccinators and vaccination officers, and that there is a greater inclination to raise the fee for procuring vaccination than for merely formal visits to record the refusal of a parent to have his child vaccinated. There is little disposition, we understand, to such an increase of the fee for the statutory visit as would so far pay an officer as to make him careless about getting the child vaccinated; hence there may be a desire even when mileage is considered not to disturb the ratio laid down between the minimum fees of 1s. and 5s.

Annotations.

"Ne quid nimis."

BACTERIOLOGICAL DIAGNOSIS.

A CORRESPONDENT draws our attention to the fact that the Camberwell Vestry has been the first vestry in London to appoint a bacteriologist to work at certain of the problems which occupy the attention of the medical officer of health. This is a new and in many ways a good departure and is certainly an experiment which is well worth careful attention, especially if the bacteriologist is to devote his whole time to the work of the vestry and to be correspondingly well paid. There can be little doubt that there is more than sufficient work to keep a bacteriologist fully employed, even though he should devote the whole of his time and energy to the appointment; whilst if he should give a part only of his time the appointment will be of value to the community. At the same time it must be evident that there may be some waste of energy and brain power if a thoroughly competent bacteriologist (however well paid) is to be expected to do a great deal of routine work which might equally well be done by skilled and unskilled assistants, and it certainly comes to be a question whether in the present state of affairs it might not be better, as we have already pointed out, to utilise to a greater extent existing facilities, and in a large community like that of London to centralise the work at two or three points. There can be little doubt that under different men very different results will be obtained, first as regards the efficiency of the work done and secondly as regards the amount of information which will be collected and made public and the value of the statistics so obtained. It is, however, well that some such experiment as that brought under our notice by our correspondent should be tried, especially as anything which is conducive to accuracy and rapidity of diagnosis will be heartily welcomed by all who are concerned in guarding the public health. It is even possible that it may be found necessary not only to have local laboratories but also to have special and consultation laboratories where work out of the ordinary routine, for which special and expensive apparatus is necessary, may be carried out. The need for bacteriological work is only just coming to be appreciated, but already there is such specialisation that it is difficult to see how any single man will be able to attack unaided (or even with the assistance to be obtained in a small laboratory) the multifarious problems with which the bacteriologist of to-day is faced. The diagnosis of diphtheria, of typhoid fever, of tuberculosis, of pneumonia, of anthrax, of cholera and the like form only a very small proportion of the work to be done. The examination of air, of soil, of water, of condemned food stuffs, and of milk will all have to be undertaken and it is quite within the bounds of possibility that laboratories will have to be founded and appointments made for the carrying on of these individual branches of work. This, however, may fairly be assumed, that whatever may be the initial cost of these laboratories and whatever it may cost to keep them well manned and equipped the direct and indirect saving to the community would be sufficient, first through the direct saving of life brought about by early diagnosis and secondly by the elimination of foci of infection and a consequent circumscription of the areas of infection and disease, during the first two or three years alone to found and endow these laboratories for a couple of score of years to come. We think that our correspondent is perfectly correct when he states that the reduction of the death-rate from diphtheria alone as brought out by the returns of the Metropolitan Asylums Board is ample justification for any vestry making arrangements to have bacteriological investigations carried on for them.

THE QUEEN'S VISIT TO NETLEY.

THE Queen's solicitude as to the condition of her sick and wounded soldiers was again shown on Saturday last, when for the third time this year she paid a visit to the Royal Victoria Hospital. A break in the bad weather lately experienced on the coast occurred, and during a portion of the time Her Majesty spent at Netley the sun shone brightly, the day being a warm one for the time of year. The portico by which the Queen was to enter the building was adorned with trophies of flags and shields and with a mass of palms, flowers, and ferns, while the corridor along which the Queen was to pass was carpeted with red cloth. Travelling from Windsor by way of Byfleet, Cosham, and Fareham, the Queen reached Netley station at 1.30 o'clock. Her Majesty was accompanied by Princess Beatrice and Princess Victoria of Schleswig-Holstein and was received at Netley station by General Sir Baker Russell, commanding the Southern district, and his staff. In attendance were the Countess of Lytton, the Hon. Mrs. Alaric Grant, and Lieutenant-Colonel Sir Arthur Bigge, while the two equerries were Major-General Sir John McNeill, V.C., and Lieutenant-Colonel Davidson. In an open carriage, a few minutes in advance of the Royal party, Lord Kitchener of Khartoum, who had joined the Royal train at Windsor, drove up to the hospital, and with him was Sir Henry Rawlinson, who was on his staff during the Soudan campaign. The Queen reached the hospital just before 2 o'clock, and was received by Surgeon-General Nash, principal medical officer, and the following officers of the Royal Army Medical Corps—Colonel Notter, Colonel MacLeod (of the Indian Medical Service), Colonel Stevenson, Lieutenant-Colonel Blennerhassett, Lieutenant-Colonel Webb, and Major Dick. Here, too, waiting to receive Her Majesty were Miss Norman, Lady Superintendent of the Army Nursing Service, and Colonel Creagh, A.A.G. at Netley. A bouquet was presented to the Queen by Miss Nellie Stevenson, daughter of Colonel W. F. Stevenson, R.A.M.C. Entering a wheeled hand-carriage which was propelled by an Indian servant the Queen passed along the corridor to the lift by which she was conveyed from corridor to corridor, inspecting the different wards both in the medical and surgical divisions of the hospital and speaking words of comfort to the wounded and stricken soldiers. In the corridor of the medical division of the hospital all the convalescent patients entitled to the Atbara and the Omdurman medal were drawn up in order of regiments, the men of the 21st Lancers being formed up on the right of the line, Royal Artillerymen of the 32nd

Digitized by Google

Field Battery came next, with the Guards on their left, and after them the Seaforths, Camerons, Lincolns, Warwicks, Rifles, Northumberland Fusiliers, and Lancashire Fusiliers. The most interesting feature of the day was the personal presentation by the Queen of the medal "For distinguished conduct in the field" to two gallant men of the Royal Army Medical Corps—viz., to Staff-Sergeant G. A. Benson and to Private A. Davidson, both of whom served in the First Brigade Field Hospital during the late campaign. During the visit the Sirdar who followed in the wake of the Queen through the various corridors and wards decorated 180 men with the medal struck by the Khedive in honour of the campaign. On Saturday last the hospital contained 800 sick and wounded men and of these the Queen saw over 600. Among the patients, apart from the sick and wounded from the Soudan, are men from India, Crete, Mashonaland, and the West Indies. Before leaving Netley Her Majesty was conducted to the operating theatre where the Roentgen rays were demonstrated by Colonel Stevenson, Princess Beatrice having the shadow of the bones of her hand thrown on the fluoroscope. The Royal visit terminated shortly after three o'clock and Her Majesty returned to Windsor by the South-Western route, arriving at the Castle at six o'clock.

THE EXPENDITURE OF THE METROPOLITAN ASYLUMS BOARD.

IN a letter from the Local Government Board referring to the managers' application for an order authorising the borrowing of a further sum of £2413 4*s.* 6*d.* in respect of alterations and additions to the South-Western Hospital the Board state that they find similar irregularities to those which occurred in the erection of the Brook Hospital on the part of the architect, and omit from the order the amount which under ordinary circumstances would be due to him as commission—viz., £62. The architect, in a letter to the managers, has defended his conduct in the case of the Brook Hospital. We do not see much evidence of any motive of personal advantage in the architect's large orders, but such motives get blended dangerously with the love of grand schemes, for which neither the architect nor the managers have the trouble of finding the money. The system is obviously not in the public interest. Let anyone contrast the scale and system of this expenditure with those of voluntary hospitals or of private individuals and they will see to what length this system has been carried. It must be checked or it will demoralise both the public and the managers. Unfortunately, it is not a subject which the party politician cares for. We must look to the Local Government Board to do its duty.

THE LAST OF LUCCHENI.

THE appeal to the Court of Cassation in behalf of Luccheni was withdrawn by his counsel *per mancanza di motivi* (for lack of grounds) and on the night of the same day (Nov. 22nd) he was removed, heavily manacled, to the prison where he is to spend the next six months in solitude. Thereafter he will be "accommodated" in the penal *oubliette* where he will be put to hard labour for the rest of his life. He is, we read in the Italian journals, "completely changed; no more the petulant cynic he was on the day of trial, but wan, dejected, prostrate (*pallido, abbatuto, accasciato*). He deplores his abominable crime," adds the reporter, "the religious sentiment dominates him, and he is haunted by fear of the eternal punishment awaiting him after death." All this was foreseen by his medical examiners who made full allowance for the vanity which was his ruling principle and which sustained him in the arrogant, the revolting self-assertion he assumed in open court. Withdrawn from the public gaze and the gratification he drew from this position he collapses at once into the "hysterico-epileptoid imbecile" of the criminal anthropologist and comports himself accordingly. The fact is not without its significance for the legislator, explaining as it does the wretched creature's disappointment that he was not tried in a canton where capital punishment (as in Lucerne) is still in force. Steeped in the spurious rhetoric of anarchism he had looked forward to the guillotine for which he had qualified—the guillotine and the scaffold, that "tribune of the socialist martyr," as his French prototype Vaillant called it. But that opportunity of ventilating his *amour-propre* is denied him and he has to share the common and ignoble doom of the Italian homicide—a mere unit among many other compatriot malefactors. We hope that the International Congress for the Suppression of Anarchism now sitting in Rome will take practical note of this collapse of Luccheni. Arrested red-handed from their crime, anarchists should not be gratified with the public trial they count upon or even with the theatrical execution they court. Vanity being in most cases their guiding motive they should under every legal safeguard and formality be brought to justice in private and be visited with its severest penalty in private likewise. Legislating on such lines the Powers represented at the Congress will have introduced an effective deterrent for such assassins, and so far the criminal anthropologist will find that he has not preached in vain. Another deterrent not unworthy of consideration is the penalty of flogging in the case of would-be or unsuccessful "Lucchenis." We have already[1] treated of this form of punishment which certainly put down garotting and which by the humiliation it combines with physical suffering would appeal powerfully to the vainglorious as well as effeminate side of such "rhetorical" specimens of the *belva umana* as Vaillant and his latest disciple. But, as we have previously urged, a deeper policy than that of the restrictive or repressive legislator must be adopted in dealing *ab initio* with anarchism and its instruments, and for this we must look to reforms inspired not merely by the forensic but by the medical innovator. The Congress of Criminal Anthropology which by a strangely suggestive coincidence met at the scene of the late anarchist crime just three years previously to its commission was not without its lessons and its admonitions to the Governments of Europe. Had these latter, particularly that of Italy, paid due attention to what was put in evidence on that occasion measures would have been adopted which might have prevented the tragedy of the Quai du Mont Blanc. Let us hope that profiting by that and similar sad experiences European statecraft will take a more intelligent interest in the next Congress of Criminal Anthropology which in the August of 1899 will assemble at the Hague.

TWO MEDICAL HEROES.

THE latest name added to the roll of the Victoria Cross is that of Surgeon William Job Maillard, M.D. Lond., of the Royal Navy, upon whom the decoration has been conferred for conspicuous bravery during the outbreak at Candia on Sept. 6th, 1898. At that date, during the landing of seamen from Her Majesty's ship *Hazard*, Surgeon Maillard, who had disembarked and reached a place of safety, returned through a perfect deluge of bullets to the boat and endeavoured to bring into safety Arthur Stroud, ordinary seamen, who had fallen back wounded into the boat as the other men jumped ashore. Surgeon Maillard failed to bring Stroud in only through the boat being adrift and it being beyond his strength to lift the man (who was almost dead) out of so unstable a platform. Surgeon Maillard returned to his post with his clothes

[1] THE LANCET, Oct. 29th, 1898, p. 1146.

Digitized by Google

riddled with bullets though he himself was unhurt. Our heartiest congratulations to Surgeon Maillard. By a curious coincidence we have to offer the same sort of congratulations to a French naval surgeon this week. In virtue of a decree dated Oct. 1st, 1898, the Cross of the Legion of Honour has been conferred upon Dr. Bartet, a young naval surgeon employed on active service in Upper Dahomey. The act of gallantry which it is designed to recognise is thus briefly described in the official record: "During the affairs of the 4th and 8th Nov., 1897, while serving with the Borgou column this officer, despising death, completed his difficult duty beside the wounded under a perfect rain of arrows."

GLYCERINATED LYMPH.

THE following minute has been issued by Mr. Henry Chaplin, President of the Local Government Board:—

Local Government Board, Nov. 16th, 1898.

I desire to place on record an expression of the value which I attach to the labours and researches of Dr. Sydney Monckton Copeman in connexion with the preparation, by the aid of an aqueous solution of glycerine, of a vaccine lymph which is free from harmful organisms. An indication of the value which is attached to Dr. Copeman's researches is to be found in the fact that Parliament has decided by Statute that this form of lymph shall for the future be used in this country. HENRY CHAPLIN.

We are glad to be able to offer our congratulations as well to Dr. Copeman with regard to his arduous researches into the question of glycinerated lymph, though of course the idea of using glycerine as a vehicle did not originate with him. But we think it is fair to say that he has raised what was formerly a mere hypothesis in this country into the region of ascertained fact. By the use of properly prepared and standardised glycerinated lymph the last shred of objection which any objector other than a pig-headed fanatic can possibly put forward to vaccination has been done away with, and we can only hope that the "tremendous experiment" upon which the Government has entered may not be attended with disaster. If an epidemic of small-pox should come it will fall hardest upon innocent children who will owe disfigurement and possibly death to the mistaken action of those whose first duty it should have been to guard them against such misfortunes.

MARGATE HOSPITAL.

WE are glad to learn that the Margate Sea-bathing Hospital is again open, having been closed by the remodelled committee of management to allow of a complete reconstruction of the drainage together with some minor but not unimportant building operations, one of the objects of which has been a much-needed improvement in the accommodation for nurses and servants. The opportunity has been taken advantage of to appropriate two small wards to the treatment of diseases not "scrofulous" in character but especially requiring sea air or sea-bathing. For many years the hospital or, as it used to be called, "the infirmary" was restricted to "scrofula," but this limitation was no part of the original design of the founders, who imposed no further limits to their charity than poverty and the probability of the patients deriving benefit from the special influences of the place. The establishment of these wards is therefore a reversion to the original design and will, it is hoped, be the means of relieving cases in more rapid succession than was done when only "scrofula" was received and that often in very chronic forms. Among other recent improvements is a new operating theatre which provides all the refinements of antiseptic surgery. The hospital is now being refilled as fast as arrangements can be made, but scarcely rapidly enough to keep pace with the public demand. The wards are pleasing and sanitary, especially those built by the late Sir Erasmus Wilson, and the chapel is no less attractive, while the situation, as close to the North Sea as it is possible for a building to be placed, ensures that no salubrious influence which sea and shore can supply will be wanting to the subjects of serious disease who go there for the ministry of nature as well as of art. We are informed that a very considerable proportion of the large sum which has been expended as indicated has been given by a member of the court of directors who is by virtue of his position well acquainted both with the necessities of the charity and with its utility.

INVESTIGATIONS AT ROME INTO THE ETIOLOGY OF MALARIA.

THE Italian observers, Grassi, Bastianelli, and Bignami, who are associated in carrying out a series of investigations at the Hospital of Santo Spirito, Rome, with the object of throwing light upon the etiology of malarial fever, have again met with success in their inoculation experiments with mosquitoes. The continuation of Dr. Bignami's original paper dealing with this line of research will be found at p. 1541 of our present issue. On this occasion only one species of these insects was employed in the experiment—namely, Anopheles claviger, captured, as before, in the adult stage in the malarious region about Maccarese. The subject of the experiment was a young man who had never suffered from malarial fever and who was received into the Hospital of Santo Spirito for hysteria about four years ago, during which time he has been constantly under observation and has had no kind of fever whatever. This man for nineteen days slept in a room in which were set at liberty from time to time numerous specimens of Anopheles claviger. On Dec. 2nd (the eighteenth day) he began to feel unwell and on the 3rd the blood on examination was found to contain the parasites of malarial fever exclusively of the common tertian type (the spring tertian of Italian writers). This form of fever is prevalent at Maccarese. Considerable difficulty is experienced in continuing these experiments on account of many of the mosquitoes dying and others refusing to feed. This is probably due to the lateness of the season.

PAUPER ATTENDANTS IN WORKHOUSE INFIRMARIES.

AT an inquest held on Nov. 28th by the coroner for Belfast in the union workhouse the circumstances of the death of Henry Savage, a weaver, aged thirty-six years, were inquired into. The coroner said that he had received information that the death of the deceased had been accelerated by improper treatment while he was in the workhouse. The wife of the deceased said that her husband suffered from paralysis and epileptic fits. Dr. MacFadden said that he had seen the deceased prior to his admission and found that he had several bedsores. He considered that the patient should be in an asylum, but on application being made to the asylum authorities they would not take him in. John Brennan said that he had attended deceased as a pauper attendant. He (witness) had said that he believed Savage was starved but he admitted in evidence that he always found plenty of food to give him. Miss Kate Megahy, a Poor-law guardian, said that she had received a letter of complaint signed "John Brennan" concerning the deceased. She had visited Savage and found his bed clean and dry. Dr. Stewart said that he had medical charge of Savage both by day and night. Savage died from degeneration of the brain and should have been in the asylum. Nurse Wright said that she was in charge of the ward in which the deceased was. There were 105 patients and she had to look after them all with the

Digitized by Google

assistance of two probationers and some paupers. The sheets about the deceased were changed three or four times a day. The jury found that the cause of death was as Dr. Stewart had stated and that Savage had received due and proper care whilst in the workhouse. They also considered that qualified nurses should take the place of pauper attendants. We are glad to be able to think that this patient did not in any way have his life shortened by want of care, but it is nothing less than a scandal that in any institution for the care of the poor one unfortunate woman should have to look after 105 patients even with the assistance of two probationers and pauper attendants in addition. We have referred to this question again and again and shall continue to do so until the scandal of pauper attendants on the sick poor is done away with. Our English workhouses are not above reproach, nor are those in Scotland; but we cannot call to mind any modern instance of one unfortunate woman being responsible for the care and nursing of 105 patients. The Belfast authorities should see that such an abomination is done away with as soon as possible. While on the subject of Irish workhouses we may mention that at the meeting of the Kilrush Board of Guardians held on Dec. 3rd it was found that the school master, the clerk, the master of the local workhouse, and all the heads of the institution had gone off to Cork Assizes. No responsible person was left in charge of the inmates who roamed about as they pleased and one inmate of weak intellect "ran amuck." Besides this there were other irregularities. The guardians described this state of things as scandalous and directed an official to take charge of the establishment. We may well ask, *quis custodiet custodes?* and should be glad to know what course the guardians will take with their officials. The whole story sounds like a tale by Lever of the days at the beginning of the century.

ROAD-MAKING.

WE have received a letter from a town councillor which shows how the doctrine of contagium vivum is permeating the minds of our local governors. Our correspondent objects to have any of the old material previously scraped off the roads used for "grout" when the road is metalled. His objection is on the ground that this material contains putrescible organic matter and he asks us whether his "theory" is correct. But road-making is a practical matter, and whether or not the material used for making the road is foul and offensive can only be answered by an appeal to facts. A heap of road scrapings very soon sweetens and the organic matter is not long in mineralising. Even if the sweepings when used for road-making should contain a small quantity of humus it would be found that it would dry less quickly than pure mineral matter and would have less tendency to fly about in the form of dust. If our correspondent's council are really going to mend their roads with dung, as he seems to suggest, then they are, of course, wrong. But we hesitate to answer his question categorically because it is of great importance that sanitary authorities should study economy and try as much as possible to utilise the materials which it is their duty to collect. It is unfortunately not common to find thriftiness in our municipal management and we hesitate to check it without hearing both sides of the question. It seems to us that road-making is often carried out in too wholesale a fashion and even country places are not content without a steam-roller. This machine, we must suppose, is capable of making good roads under certain conditions but those conditions appear to be rarely met with near London. The pressure per square inch of a steam-roller is less than the pressure of the wheels of a heavily laden waggon and the result is that the steam-roller-made road is very liable to "pocket." For a few weeks, of course, the road is smooth enough, but very soon it "gives" for the reason stated and then the cyclist who traverses it goes along bumping and grunting and perhaps swearing. We inspected a by-road not long ago which after a neglect of about two years had been made up with a steam-roller. The metal was huge and had been merely "chucked" upon the surface of the road. Then came the steam-roller, jerking and roaring over it, with the result that it broke two gas-pipes and made a huge depression at one end. This was filled up and then came, after a lapse of a day or so, the steam-roller on a second visit. This time it broke two water-pipes and we only wonder whether it broke any drain-pipes. Would it not be better to copy the French and place our by-roads, at least, under the care of individuals who should work perpetually upon them—sweeping, watering, and mending. A "stitch in time" is a good old proverb and it is very doubtful economy to allow a road to get into a maximum state of disrepair. The man who had charge of a mile or two of by-road flanked by villas would, if he did his work well, be sure of a Christmas-box, and the work is of a kind which would keep many an elderly man out of "the house."

DEATH UNDER CHLOROFORM.

A DEATH under chloroform occurred recently in St. Bartholomew's Hospital. The patient, a butcher, aged forty-two years and weighing between 21 st. and 22 st., was admitted suffering from an old injury to his thigh. There was a large abscess pointing in the upper part of Scarpa's triangle and the thigh was in an erysipelatous condition. The temperature was 101·2° F., the heart-sounds were normal, but the lungs were emphysematous. There was some orthopnœa, partly due to the obesity of the patient and partly no doubt to the emphysema. Four hours after admission the anæsthetic was administered by a house physician. Nitrous oxide gas followed by ether was given in order to stimulate the circulation as fatty change in the myocardium was suspected and the heart's action was weak. The patient, however, breathed badly and became cyanosed. The induction of anæsthesia being complete the anæsthetic was changed for chloroform, which was given from lint. To relieve the diaphragm from the pressure of the abdominal viscera the man was turned upon his side and the head lowered. The breathing became less laboured, being regular and somewhat shallow, but the face remained congested. The patient was kept only lightly under the anæsthetic, slight movements of the arms and legs being made during the semi-anæsthesia. The operation was completed, a shallow inspiration was then taken, and subsequently respiration ceased. The tongue was drawn forwards, a ligature being passed through it, and ether was injected into the tissues of the cardiac area. One feeble inspiration was made, but no more. Artificial respiration was ineffectual in restoring vitality. The pulse stopped and the respiration ceased. The necropsy revealed advanced fatty degeneration of the heart and other organs. Death in this case appears to be due to failure of the diseased heart, possibly owing to shock, as it appears that the patient was but very slightly under the anæsthetic, and no doubt it was accelerated by the diseased condition of the man's lungs, his posture, and the fulness of the venous system as evidenced by the congested face and laboured breathing. The case was clearly one of extreme difficulty and even had the operation been performed under a local anæsthetic it is by no means certain that the mental shock might not have brought about the very result that occurred during the administration of the anæsthetic. The carefully prepared notes (for which we are indebted to Mr. Jameson) do not mention to which side the man was turned. Whether the diaphragm is helped by the lateral decubitus in such cases is, we believe,

Digitized by Google

open to doubt, and there is always the danger of still further hampering respiration and circulation by compressing one or other lung in that posture when the patient is very heavy, especially when emphysema is present. The initial use of gas and ether in this case may be adversely criticised by some but it certainly possessed the advantage—an important one in the present instance—of avoiding the stage of excitement so common when chloroform is used in the induction of anæsthesia. Probably had the development of cyanosis been foreseen the brief operation would have been conducted under nitrous oxide gas mixed with oxygen, which answers well in short cases, although it must be admitted that it is not an ideal anæsthetic for such persons as the patient is described to have been in the case in question.

LARGE FAMILIES AMONG THE POOR.

AT an inquest held on Dec. 2nd by Dr. Wynn Westcott at Bethnal-green on the body of an infant found dead in bed the mother of the deceased mentioned that she had fifteen children. The coroner remarked that he could not understand how it was that the poor managed to keep such large families, whereupon a juror remarked: "One or two don't make no difference. Some grow up and help to keep the others." After all, there may be more sound sense in this argument than might at first sight be supposed. Everyone who has any experience of work among poor people knows how kind the poor are in taking in an extra child for nothing very often, and sometimes for a small weekly payment. We do not, of course, refer to baby farmers, but as a matter of fact the charity of the poor to one another is above all praise, and so perhaps the large family may not be so undesirable after all. The great difficulty in connexion with such is not so much clothing or feeding but proper house-room, and to find this with the exorbitant rents which are being daily demanded in London is almost impossible.

THE ANNUAL REPORT OF THE ARMY VETERINARY DEPARTMENT.

THE usual annual report of the Army Veterinary Department has recently been completed by the Director-General, Veterinary-Colonel Duck, C.B., F.R.C.V.S. It consists of a general summary of the diseases met with amongst the army horses and transport animals at home and abroad. In the Home Department the number of patients amounted to 65·12 per cent. of the average strength, being greatest in the Army Service Corps which has the Young Horse Depôt attached to it and lowest in the Military Police. It was noticed, as has been the case before, that the percentage of admissions to treatment was higher in horses about four or five years of age than in those of more mature years. It is a matter of great congratulation to know that glanders is still absent. One suspicious case occurred amongst the animals at Shorncliffe in November, 1897, but a careful post-mortem examination and the use of the mallein test amongst the in-contact horses demonstrated beyond dispute that the disease was not glanders. In Egypt, from which country the report is made by the senior veterinary officer, Veterinary Captain Blenkinsop, the absence of glanders is also noted, although 69 cases of this disease were reported by the Egyptian civil authorities. The Government stables, however, had a narrow escape from becoming a centre of contagion, as a private pony standing in one of them showed suspicious symptoms and after reacting to mallein was destroyed, the necropsy confirming the existence of the disease. All the animals in the same stable were promptly tested, but none reacted and the disease has not again reappeared. Veterinary-Captain Blenkinsop suggests that as remount horses and mules are largely obtained from Syria, where glanders exists to some considerable extent, all animals should be tested before being admitted to the troop stable. In South Africa outbreaks of glanders occurred at Etchowe or Pietermaritzburg. Mallein was employed and all animals which reacted were destroyed. Every precaution was adopted and the disease appears by the last reports to be stamped out. Mortality from "horse sickness" was very heavy and an unusually large number (no less than 119) of animals died from colic due to the ingestion of large quantities of sand. The latter cases occurred at Ladysmith, where the animals were picketted out in the open on a sandy soil which they continually licked, the sand accumulating in the intestine and causing complete obstruction. In the Army Veterinary School the usual classes were held for officers and farriers, examinations being held and certificates granted to those who were successful. From the Vaccine Institute lymph was issued for 71,103 people, the average yield from each calf being sufficient for 4345·25 persons, the total expenses for the year, including cost of calves, instruments, &c., being only £91 9*s.* 3*d.* Lymph is now supplied from here to the navy as well as to the army, a request to that effect having been received from the Admiralty.

BILATERAL ACUTE LABYRINTHITIS.

IN the *Intercolonial Medical Journal of Australasia* of Oct. 20th Dr. Percy Webster relates a case of this very rare disease. A healthy lad, aged ten years, one day looked pale and ill. He vomited, became delirious and complained of pain in the head; he had to be held down in the bed. The acute delirium lasted 11 hours, after which he was quiet but lay muttering. He called out with pain when touched; moving the limbs seemed to cause great suffering. At times he would lie with his back arched and his head retracted. He was ill for about two months and became very thin. He had giddiness and after his recovery staggered at times especially in the dark. Deafness was noticed before he recovered from the delirium and remained permanent; it was total both for bone and aerial conduction. He complained of pain and constant buzzing in his ears. The fundi were normal, the knee-jerks were active, and there was neither ankle clonus nor paralysis. As the history was only obtained from his friends it was impossible to say whether the labyrinthitis was primary, or associated with meningitis, pneumonia, typhoid fever, or one of the exanthems, or whether it was secondary to otitis media.

THE PURPURA OF CHILDHOOD.

AT the recent Congress on Gynæcology, Obstetrics, and Diseases of Children, held in Marseilles, Dr. Leon Perrin discussed the pathological significance of purpura in children. This term, he reminds us, no longer stands for the name of a disease but of a symptom. The condition of blood-stasis which it denotes, whether merely an intense congestion with capillaries unruptured or a true extravasation, is in the great majority of cases due to an infective process—a toxæmia. Even the rheumatic variety, he maintains, ought to be relegated to the same series as those of obviously septic origin as being also toxic, though by means of a different toxin. Purpuras associated with syphilis, with the eruptive and other infectious fevers, with septic pleurisies and pneumonias, are necessarily of this character. In the same connexion a reference to two cases in which the presence of staphylococci was demonstrated in the blood is interesting. Dr. Perrin also quotes the observations of de Boeck-Renher, Hutinel, Le Gendre, and others to prove the frequency with which the tonsil serves as the chief point of entrance for the germs of disease. But whether this gland, or the skin, or the gastro-intestinal canal provides the nidus, the later action of toxic products

Digitized by Google

is essentially the same in all cases. They penetrate the tissues, alter the composition of the blood, and by attacking either directly the capillaries or indirectly the vaso-motor centres reveal their presence by the sign of purpura. Neither is the influence of the non-vital agents without significance in this connexion. Various drugs—mercury, iodoform, arsenic, and others—afford the same purpuric signs after a period of use and they doubtless act by means of the same physical mechanism. Cachectic and other allied morbid states also do this by developing a variety of auto-toxins. Purely physical and metaphysical forces—as cold, emotion, &c.—have, on the other hand, merely a predisposing effect. Not the least interesting details in this interesting paper are those relating to age. Purpura, as is well known, is very frequent in childhood, more so than in adult life. In this respect it resembles the eruptive fevers. From four to ten years is the most usual age-period for its appearance, though it is fairly common up to twenty. Dr. Perrin, however, quotes cases observed by Steffen some of which occurred at a much earlier stage of life—viz., 1 at thirty-six hours, 1 at eight days, 1 at a fortnight, 1 at six weeks, and 16 from three to nine months after birth.

ALLEGED ILL-TREATMENT OF A PATIENT AT THE LONDON HOSPITAL.

THE evidence given at an inquest held by Mr. W. E. Baxter at the Whitechapel Infirmary last week should certainly cause the governing body of the London Hospital to institute an inquiry in reference to a patient whom the evidence showed to have been turned out of the hospital into the street in a very unusual manner. Dr. Frazer stated that the man was admitted into the hospital on Thursday, Nov. 3rd, "but behaved so indecently that at last the nurses refused to go near his bed." The witness, however, at a later stage of the inquiry amended this statement by saying: "What I really meant was that I felt inclined to refuse to allow the nurses to attend the patient on account of his behaviour." Dr. Frazer also stated that the Whitechapel Infirmary and two other infirmaries had been applied to and in each case admission was refused to the deceased. As far as the first-named nstitution was concerned it was proved that that statement was incorrect. The patient was, in fact, led outside the gate of the hospital by a porter, when he sat down on the pavement until found by a policeman who removed him to the infirmary where he died from "softening of the brain." A porter from the London Hospital stated that he informed a constable on point duty outside Whitechapel railway station that the deceased was going to be put out of the hospital. The jury returned a verdict in accordance with the medical evidence, and added: "We desire to express our deep sorrow at the way the poor fellow was turned out of the hospital, and we are of opinion that the house governor of the hospital acted in a very high-handed manner in having the man expelled in such a casual way without seeing that he was properly attended to outside." With the evidence at present before us we are forced to agree with this reprimand, but we trust that further investigation will show that the action of the authorities was not so hard-hearted as it appears. All who have had experience in hospital management know how difficult it is to deal with such cases at a general hospital, and young house physicians and house surgeons acting with perfectly good intentions are occasionally apt to turn patients over to the police without due examination of their mental condition. It should have been remembered that indecent language and behaviour are very common symptoms of insanity, and the house governor should have ascertained whether the physician in charge of the case was of the same opinion as his junior before consenting to the man being turned out into the street. Such an event is likely to cast discredit upon the management of a most noble institution and a satisfactory explanation should be as widely spread as the report of the verdict of the jury has been.

THE WATER-SUPPLY OF EAST LONDON.

THE East London Waterworks Company resumed the constant supply in Poplar, Limehouse, Millwall, Ratcliff, Bromley, Loughton, Chingford, Chigwell, and Buckhurst Hill on Monday last and the directors have stated their confident expectation of returning to the constant supply in every part of their district by the end of the present week.

THE BERTILLON SYSTEM OF MORTALITY STATISTICS.

A DECISION the importance of which can hardly be estimated as yet was reached at the recent meeting of the American Public Health Association, held at Ottawa, Canada, in September last. The following resolutions, which had been submitted by the Committee on Vital Statistics at Philadelphia in 1897, were favourably reported by the Executive Committee and were then unanimously adopted by the association: The American Public Health Association recommends that the Bertillon classification of causes of death be adopted by all the registrars of vital statistics in the United States, Canada, and Mexico as soon as the change from the systems now in use can be conveniently made. The Committee on Nomenclature of Diseases and Forms of Statistics (now the Committee on Demography and Statistics in their Sanitary Relations) has been authorised to have printed and circulated amongst the registrars of the three countries a circular containing these resolutions, the report of the committee on which they are based, the three alternative forms of the Bertillon classification, with explanatory notes on inclusion of terms and practical rules for compilation, and a list of the registration offices adopting the same. A proposal will be made for an international alliance between the registrars of the three countries included in the association and the registrars of France and other countries now using, or which shall hereafter adopt, the Bertillon system, and definite plans for such an alliance are to be submitted for action to the next annual meeting of the association.

"TYPHOID PLEURISY."

THE *Semaine Médicale* of Oct. 19th contains a valuable paper by M. Achard on this subject. Pleurisy occurring in typhoid fever may result from the action of the typhoid bacillus or from some other infection. Typhoid pleurisy may assume several forms—sero-fibrinous, hæmorrhagic, or purulent. In some cases the pleurisy seems to have preceded the typhoid fever just as typhoid pneumonia may. The effusion may also show itself during the course of the disease. Thus a man, aged twenty-six years, with all the usual symptoms of typhoid fever, had dyspnœa and dulness at the base of the left lung. Puncture showed the presence of fluid a little cloudy and containing red and white corpuscles. On several occasions during a month serous fluid was obtained by puncture which always contained the typhoid bacillus in pure culture. The signs disappeared and he recovered. In another case, in a young woman, an empyema formed. At the end of the third week there was a friction sound at the left base; the temperature fell to normal and convalescence was apparently insured, but dulness was found at both bases and pyrexia again appeared. An empyema formed on the left side. A litre of pus was evacuated which contained the typhoid bacillus in pure culture. Resection of a rib and drainage were carried out and the patient recovered. Why does the typhoid bacillus

Digitized by Google

produce pus in some cases and not in others? A categorical answer cannot be given, but analogous cases can be cited. The swellings of osteo-myelitis are sometimes abortive and resolve without suppuration. The spleen is constantly the seat of bacillary foci in typhoid fever, but abscess results only exceptionally. In experimental inoculation of the typhoid bacillus pus is sometimes produced, sometimes not. The same is true of the colon bacillus. Again, streptococci and staphylococci, microbes usually pyogenic, are sometimes present in non-suppurative lesions. Finally—a very complete analogy—the tubercle bacillus can induce fibrinous, serous, hæmorrhagic, or purulent pleurisy. As to the treatment of typhoid empyema M. Achard recommends postponing operation until the intestinal ulcers are healed and the patient has recovered strength. This course is possible as typhoid empyema as a rule does not run a rapid course and has not a tendency to invade other parts or to give rise to general infection—septicæmia, for example—as has empyema induced by streptococci.

THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

IN accordance with the plan set forth by His Royal Highness the Prince of Wales a Committee of Inquiry has visited the various hospitals which applied for a share in the Prince of Wales's Hospital Fund in the summer. The committee was composed of nearly equal numbers of medical men and laymen, if we exclude Sir Trevor Lawrence who may be reckoned as both, and its report will doubtless when issued be of great service to the Distribution Committee in allocating the Fund to those institutions which are not only needy but deserving. The Executive Committee of the Fund, of which Mr. Hugh C. Smith, the Governor of the Bank of England, is treasurer, has issued an appeal for funds, apparently based upon information received from the Committee of Inquiry. A sum of £30,000 is still wanted to meet the minimum necessities of the hospitals for the present year. Last year the Prince of Wales's Fund was the means of opening 180 beds which before had remained closed for want of money. We are glad to see that the appeal points out that it is wasted generosity to build new wards and hospitals when so many of the existing wards are perforce empty and useless. The Sirdar has within a very few days managed to collect the sum of upwards of £70,000 for the Gordon Memorial College in the Soudan. We congratulate his lordship most heartily on the success which his efforts have attained, but we would remind those who are blessed with this world's goods as well as those who are not rich that the needs of the sick poor are paramount. We cannot but also remind the authorities responsible for the management of our metropolitan hospitals that a great deal of their charity is expended not only upon unworthy objects, but also upon people from all parts of the country who could be just as well treated nearer their own homes.

THE INDIAN AND COLONIAL ADDENDUM TO THE BRITISH PHARMACOPŒIA OF 1898.

IT is not often that it is possible to criticise material for publication which has not yet reached a final stage. This opportunity has been afforded by the receipt of the report from the Pharmacopœia Committee on the proposed Indian and Colonial Addendum to the British Pharmacopœia of 1898. This report contains suggestions for consideration by the medical and pharmaceutical authorities in India and the colonies and these suggestions cover some twenty-two pages. These pages include a list with descriptions of drugs already proposed by Indian and colonial authorities for official recognition, but the most cursory consideration of the information indicates that many of the descriptions are avowedly imperfect, while in some places no description of any kind is given. It would appear, however, that these pages have to be transmitted to various medical and pharmaceutical bodies in India and the colonies with the aid of Her Majesty's Privy Council and it has therefore been deemed essential that this raw material should be passed and approved by the General Medical Council. The suggestions evidently are to be regarded only as a first rough sketch, which is to be finished with the coöperation of the Indian and colonial authorities who are requested to criticise and amend the descriptions and to give such other suggestions as may be deemed desirable to render the Pharmacopœia, with this addendum when complete, an authority which shall meet the requirements of the various colonies and dependencies. There is, however, even in this incomplete form abundant evidence that the drugs here mentioned are not intended as mere substitutes for drugs entering into preparations now official. They are intended only for local use and therefore possess very little interest for has practitioners in this country.

THE Peninsular and Oriental steamer *Caledonia* arrived at Plymouth on Dec. 7th, having come direct from Bombay without calling at any Mediterranean port. While in the Red Sea two Lascars developed symptoms of plague. They were landed at Suez and no further outbreak occurred. Dr. Bulstrode from the Local Government Board and Mr. F. M. Williams, the port medical officer, boarded the *Caledonia* immediately she arrived in the Sound. All the crew and passengers were inspected and 160 of the latter who landed at Plymouth had their names and addresses forwarded to the local authorities of their respective destinations. The ship then proceeded to London.

THE Church Society for the Promotion of Burial, Funeral, and Mourning Reform recently appealed to the Prime Minister to carry out the recommendations of the Select Committee on Death Certification. Lord Salisbury has promised to give the matter his attention.

THE Queen has given to Edward Divers, M.D., Professor in the Imperial University, Tokio, Japan, Her Royal licence to accept the Insignia of the Imperial Order of the Sacred Treasure of the Second Class, conferred upon him by the Emperor of Japan.

AT the Quarterly Court of Governors held on Dec. 7th, it was unanimously agreed to elect Mr. Frederick Treves a consulting surgeon to the London Hospital. Mr. Treves has been a surgeon to the hospital since Sept. 23rd, 1879.

THE annual general meeting of the constituents of the Metropolitan Hospital Sunday Fund will be held at the Mansion House, E.C., on Monday next, Dec. 12th, at 3 P.M.

BRIGHTON, HOVE, AND SUSSEX THROAT AND EAR HOSPITAL.—This hospital, the first portion of which has just been erected, was opened by his Grace the Duke of Norfolk on Nov. 29th. The building is from the designs of Mr. Cawthorn, architect, of North-street, Brighton, and the exterior is treated with red brick and terra-cotta. The site is upon the slope of a steep hill at the upper part of Church-street, Brighton, and the building consists of five floors. The out-patient department occupies the ground floor. The first floor has a ward for males with eight beds and the operating theatre is on this floor, the walls being tiled and the floor of marble terrazzo paving. The ward for females with eight beds is on the next floor and there are several detached rooms to be used as separate wards as well as nurses' rooms, &c., on each floor. On the top floor are the rooms of the servants and night nurses.

QUACKS AND ABORTION:

A CRITICAL AND ANALYTICAL INQUIRY.

I.

IT has been for some time past a matter of comment that a large number of advertisements are published in newspapers in this country inviting women to purchase nostrums therein referred to for the purpose of removing what are usually described by the advertisers as "irregularities," "suppressions," and "obstructions," the irregularities, suppressions, and obstructions meant being clearly those of the menses. The advertisement as a rule claims to deal with obstructions, &c, arising from *all* causes and the impression left upon the medical reader is that many of these advertisements are thinly veiled invitations to purchase and to use the advertised articles for the purpose of procuring miscarriage, pregnancy being not only the most common but the only common cause of the cessation of the menstrual flow. We shall later discuss the question of the frequency of amenorrhœa from causes other than pregnancy and the desirability of treating the condition with a quack medicine regardless of the causes from which it may have arisen. The obvious aspect of these advertisements is the more important. To this we turn first.

Recent trials have drawn considerable attention to the subject of criminal abortion and the law affecting it, and it was evident even before the arrest of certain persons yet to be tried upon a charge of alleged blackmail that the procurement of miscarriage was not the only criminal practice which might be facilitated by the publication of the advertisements in question. In these circumstances their continued appearance with impunity and profit (for advertisements are not inserted gratis, even by the most needy periodicals or paid for year after year if they do not bear fruit) seemed remarkable, and we decided to inquire whether this could be accounted for by any defectiveness in the law or by some misconception of our own as to the facts. We may also say that we had not only resolved upon making the inquiry that now follows before the persons at present awaiting trial attracted the attention of the law, but we had actually commenced our inquiry, having obtained the materials for the greater part of the laboratory tasks which form part of this investigation.

With regard to the law, by 24 & 25 Vict. cap. 100, sect. 58, "Every woman being with child, who, with intent to procure her own miscarriage, shall unlawfully administer to herself any poison or other noxious thing ..... and whosoever, with intent to procure the miscarriage of any woman whether she be or be not with child shall unlawfully administer to her or cause to be taken by her any poison or other noxious thing ..... with the like intent shall be guilty of felony, and being convicted thereof shall be liable ..... to be kept in penal servitude for life," &c. By Section 59 of the same Act, whosoever shall unlawfully supply or procure any poison or other noxious thing ..... knowing that the same is intended to be unlawfully used or employed with intent to procure the miscarriage of any woman, whether she be or be not with child, shall be guilty of a misdemeanour, and being convicted thereof shall be liable to be kept in penal servitude for the term of three years, &c. By 24 and 25 Vict. cap. 94, sect. 1, accessories before the fact to a felony are punishable as if they were principal felons, or may by Section 2 be charged as substantive felons if they have "counselled, procured, or commanded" any other person to commit any felony. It seemed, therefore, fairly clear that the persons to whose advertisements we have referred, should they *in fact* carry on an unlawful trade, were tolerably well provided for by the law, while their customers shared their susceptibility to legal process. It became important, therefore, to ascertain with certainty whether the business of selling these nostrums was of the nature which in our view the advertisements suggested and were intended to suggest, or whether the business was correctly indicated by that to which we have referred as being rather a thin veil designed to protect it from too curious observation[1]

In order to make our meaning quite clear we give three advertisements.

Ladies, Consult Madame Wood, LADY SPECIALIST ON ALL FEMALE AILMENTS, IRREGULARITIES, AND OBSTRUCTIONS, however obstinate. Save Time, Trouble, and Expense by consulting an Experienced Specialist AT ONCE. My Remedies are the most powerful and strongest on earth, effectual after all others have failed. May be taken by the most delicate. A lady writes: "NONE HAVE EVER DONE ME ANY GOOD BUT YOURS, NOTWITHSTANDING THEIR SO-CALLED TESTIMONIALS." Madame Wood may be consulted daily, or by letter, enclosing stamped envelope. Price of Mixture 4s. 6d., extra strong 11s., secretly packed. By post 3d. extra. 20, GREAT AVENHAM-STREET, PRESTON, LANCASHIRE.

Ottey's Strong Female Pills quickly and certainly remove all OBSTRUCTIONS arising from any cause whatever, where Steel and Penny Royal fails. Invaluable for married women. By post, under cover, for 14 and 33 stamps, from THOMAS OTTEY, Chemist, 32, Hagley Road, Birmingham. Please mention the *Derbyshire Times*.

Apiol and Steel Pills for Ladies.—A French Remedy for all Irregularities. Obtainable only from Martin, Chemist, Southampton. Price 4s. 6d., post free.

Any one who cares to see more of this sort of stuff than we have space to print will find it in the files of some London daily papers and of country newspapers which have a large circulation among outwardly respectable people, but chiefly in certain Sunday or weekly papers, in small provincial sheets, and in other publications which from their nature are read by those female members of the community most likely to feel the need of the relief promised and least likely to hesitate in accepting the specious offers made to them. Since the commencement of the magisterial inquiry into the charges of alleged blackmailing these advertisements we notice have been omitted from some at least of the papers which usually devoted considerable space to them, and in others they are less conspicuous than formerly. They have not, however, wholly disappeared, nor does it seem to us likely that they will unless their character is fully brought home to the police whose duty it is to prevent crime, and to newspaper proprietors who are presumably not desirous of assisting the commission of crime even when they are content to make a profit and plead ignorance of the true nature of its sources. In any case the trade, though it may be considerably crippled if it cannot be advertised in the newspapers, will probably go on to some extent, and it is well that what the trade is should be thoroughly understood by all. It will be seen that no advertiser employs the word "miscarriage" or invites his customers to "try our pills for abortion," but we do not expect to be contradicted when we say that some at least hardly attempt to cloak their obvious meaning under any pretext, while others, no doubt, vaguely or in terms refer to irregularities of menstruation not necessarily arising from pregnancy. It will occur, however, to anyone reading with the most open and unprejudiced mind that whatever they are capable of effecting, and whatever effect their vendors, if pressed to be explicit, might claim for them the goods advertised are liable to be bought without inquiry by ignorant women anxious to rid themselves secretly of possible offspring.

The compounds therefore which we are discussing and of which we have purchased a selection (now before us) must fall under one of two heads, each having two subdivisions—except in so far as some may be sold indifferently for the two purposes. These heads and divisions are: I. Professed emmenagogues (*a*) efficient and (*b*) non-efficient. II. Professed abortefacients (*a*) efficient and (*b*) non-efficient. It is also clear that the question whether an individual nostrum falls under head I. or head II. is one of inference from the circumstances of sale and from the interpretation of the advertisement or of the documentary matter accompanying it when sold; while the question of the subdivision in which it is to be classed according to its efficiency or non-efficiency must depend upon analysis of the nostrum itself.

Believing the whole matter to be of importance to the public and to the medical profession we have purchased their pills or mixtures from a large number of the most prominent advertisers.[1] This has been done, as a rule, in the first instance by the writing of a letter in the character of a servant or woman of humble station enclosing payment and

[1] To prevent error we would point out that the remarks which follow refer to such advertisers as a body and not to the three persons whose advertisements we happen to have singled out for notice above.—ED. L.

Digitized by Google

asking for the goods to be packed secure from observation; while in some cases the thing advertised has been simply ordered and paid for. Occasionally where a second letter has been written pregnancy has been avowed. We have made analyses of a considerable number of the pills and potions we have received and the results of our analyses we propose to submit in detail to our readers together with extracts from the printed or written matter which in all cases accompanied the goods sent. Before doing this, however, there are one or two points to which reference may conveniently be made now, because they are in the nature of criticism of features which occur frequently in the printed promises of the vendors, and because to treat of them at once will clear the ground and prevent repetition hereafter.

The printed matter accompanying the boxes and bottles sent out by these persons leaves little doubt as to what the vendors profess to sell, or are willing to be understood to sell, as long at least as buyers will send their orders without specifying too closely what they require. For example, where a box of pills is accompanied by a leaflet which announces others, "extra strong, 11*s.*," and others, "special strong, 22*s.*" and on the same paper is recommended a "Positive Preventive, a Compound Quinine Injection that Never Fails," no one can help drawing conclusions adverse to the advertiser, while the inference is not weakened by finding an "Invaluable Book for Women" recommended below with the title, "How to Limit Your Family, and Woman her Complaints." Whatever such an advertiser may sell actually, or whatever he may possibly declare the object of his sale to be if closely pressed, it is fairly obvious that many pregnant women would purchase his "special strong" pills at 22*s.* with one idea only in their minds. Another advertiser, however, a lady, leaves less room for doubt as to her interpretation of the word "irregularities."

Her catalogue concludes with a list of her "Infallible Safeguards for Preventing Irregularities." These we find to be—

"Soluble Pessaries (wife's use),
"Rubber Preventives (husband's use), and
"Preventive Pessaries (wife's use)."

This page, which contains further details of similar character, would not be legal evidence against any other person, but we cannot help believing that emanating from one in the trade it supplies the trade meaning of an ambiguous term.

Another point frequently observable in the literature of this trade is the recurrence of a warning to the effect that "this must not be taken by those expecting to become mothers." We find it, for instance, on the first leaflet referred to above, that of the author of "How to Limit your Family and Woman her Complaints." It is a notice which may be interpreted in two ways. It may be taken as a warning that what is sold as an emmenagogue should not be used by a pregnant woman because it is also an abortefacient. Or it may be in some cases an indication of the alleged character of what is sold which is purposely given to serve as an invitation to unlawful practices. In either case it is likely that a pregnant woman, ignorant and desperate, may purchase the "remedy" without further question in hopes that it may induce miscarriage.

The third general feature of the printed matter to which we have to allude is the character of the testimonials. These, as in the case of most patent medicines, occupy a considerable space in the various booklets and leaflets circulated by the vendors and as in the case of most patent medicines they show that if they are genuine the quack cannot complain of ingratitude on the part of his customers. Indeed, it is this particular point of gratitude to which we wish to call attention. Many of our readers have no doubt met with grateful patients; many, too, have attended women with success whose menses have from various causes (not including pregnancy) become scanty or altogether absent. Have any of them in the circumstances received such letters as these?

DEAR ——,—It gives me great pleasure to say that after taking the first bottle of your wonderful medicine all came about as I desired after eleven weeks of misery and anxiety.

DEAR ——,—I was delighted to find myself all right last night after finishing the "specific." My anxiety and suspense for nearly four months cannot be described. Such a friend as you would indeed be difficult to find. I had given up all hope. Many, many thanks for your noble letter and wonderful medicine.—Gratefully yours,
MRS. ——.

DEAR ——, I now take the pleasure in writing you these few lines and glad to say that the pills have done me good for now I am alright. I am sending now for Dr. ——'s pessary. With my best wishes for your pills. MRS. ——.

We have only to add to this last letter that Dr. ——'s pessary is described lower down as a "real preventative of conception."

It must not be supposed that we have made an exhaustive inquiry into the materials used by each and every advertiser whose wares are proclaimed in suspicious terms; they are too numerous. Some no doubt trade under many names, but still there are evidently scores of persons who seek to get a living by—to use their own term—curing irregularities in women. Some are not as bad as others. Some, no doubt, who advertise "female" pills do not even profess to deal with pregnancy at all and are not desirous of being thought to do so. They reiterate the maxim that "prevention is better than cure" and trade principally in what are known as Malthusian appliances—one of them including among these appliances an apparatus for irrigating what he terms the "virginia."

One incident struck us as material in its bearing on the promise of secresy made by so many of the advertisers. We received a pamphlet, while we were in communication with the more prominent advertisers, advocating certain pills, the sender being a person to whom we had not written at all and whose name was unknown to us. The explanation was apparently contained in a passage printed therein: "I am not connected with any other firm whatever. I only buy the names and addresses of others who profess to cure you and cannot." We are sorry for those who write in more genuine need than ourselves if this trade in names and addresses is largely practised. We did not write for any of the wares, and shall make no further reference to the pamphlet than to quote a passage from it which speaks volumes for the general culture and technical knowledge of its author: "Many long years of my life, full of travel and experience, has been devoted to the study of the best method of curing female obstructions and irregularities, suppressed courses, anæmia, amenorrhœa, catamenia, dysmenorrhœa, emmenagogue, chlorosis, epistaxis, systolic murmurs, &c.; and I am not egotistical when I say with all truth that I have been successful beyond my dreams."

In our next article we shall proceed to the analysis of certain pills and potions and the discussion of the professions of some of the vendors. In some instances, at all events, it will be found that the analysis and the words of those who for years have advertised their goods so openly in the press leave no question as to the qualities claimed for them.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary meeting of the Comitia was held on Dec. 1st, Sir SAMUEL WILKS, Bart., President, being in the chair.

A Licence to practise physic was granted to Mr. J. J. Urwin, Glasgow and Leeds.

The PRESIDENT announced that he had invited Dr. Poore to be the Harveian Orator for 1899 and Dr. Foxwell of Birmingham to be the Bradshaw Lecturer.

The following communications were received:—

1. From the Board of Trade, Nov. 11th, requesting the College to appoint two members of a committee for revising the Medical Scales of Passenger Ships. Dr. Tirard and Dr. Sidney Phillips were asked to represent the College.

2. From St. Bartholomew's Hospital Medical School, Oct. 28th, on the Effect of the New Regulation of the Conjoint Board with respect to the Period of Dissections. Dr. CALVERT and Dr. CURNOW made a few observations, but the PRESIDENT said he thought it was not the time to discuss the question in full. It had been before the Royal College of Surgeons of England and would come before the Committee of Management. The REGISTRAR moved that the letter be referred to the Committee of Management and that discussion should be postponed until their report was received. This was carried. A letter from Dr. Isambard Owen was also referred to the Committee of Management. The PRESIDENT hoped the deans or wardens of the other medical schools would also express an opinion on the subject and report to that committee.

3. From the Imperial Military Academy of Medicine

Digitized by Google

St. Petersburg, Oct. 30th, inviting the College to send representatives to the celebration of the centenary of its foundation on Dec. 18th (30th N.S.), 1898. The President undertook to invite some one to represent the College.

4. From the London County Council, Nov. 11th, thanking the College for the report of the Special Committee on Infectious Puerperal Diseases.

5. From the Queen Victoria's Jubilee Institute for Nurses, Nov. 2nd, informing the College of Her Majesty's approval of Sir Dyce Duckworth as representative of the College.

6. From the Secretary of the Royal College of Surgeons of England, reporting certain proceedings of their Council on Nov. 10th.

7. From the Charity Commissioners, reporting the Scheme for the Management of the Chelsea Physic Garden. The scheme provides:—1. For the maintenance of the garden and laboratories. 2. For instruction in and investigation of pharmacology, &c. 3. For the appointment of administrators and trustees and a committee of management. As it at present stands the scheme provides that the College should send one representative alternately with the Society of Apothecaries of London; Dr. HENSLEY proposed, and Dr. LAUDER BRUNTON seconded, a resolution that a request should be sent to the Charity Commissioners that the College and the Society of Apothecaries of London should have the same representation as the Royal Society. This was carried.

A report was received from the Committee of Management containing the synopsis of practical pharmacy, and also a request that the committee should be empowered to consider the question of an examination in practical physiology, to take the opinions of the several medical schools, and to report to the Royal Colleges on a future occasion.

A report was received, dated Nov. 7th, from the Leprosy Committee appointed on Oct. 27th. The report was as follows:—

Your committee beg leave to report as follows:—

That the communicability of leprosy, by direct or indirect means, from lepers to the healthy, must now be accepted as an established fact, the evidence in support of this belief being conclusive; and that there is no evidence of the disease arising or spreading in any other way.

Your committee are therefore of opinion that the conclusions stated in a resolution unanimously adopted by the Conference on Leprosy held at Berlin in October, 1897, and set forth at p. 194 of the official report of the Conference, ought to be accepted in their entirety.

This resolution is in the following words:—

[*Translation.*]

1. In all countries in which leprosy occurs in *foci* or is widely distributed isolation is the best means of preventing the spread of the disease.

2. The system of compulsory notification, supervision, and isolation as carried out in Norway should be recommended to all nations possessing local self-government and an adequate number of physicians.

3. It must be left to the legally constituted authorities, after consultation with the sanitary authorities, to determine the special regulations which must be adapted to the special social conditions [of each country].

But your committee would dwell with especial emphasis upon the last paragraph of that resolution, recommending careful consideration of the social and political conditions of each particular country.

An animated discussion followed as to whether all forms of leprosy should be included and whether the recommendations should apply to this country. Several Fellows expressed their opinions or offered suggestions, including Sir William Broadbent, Dr. Radcliffe Crocker, Dr. Cullingworth, Sir R. Douglas-Powell, Sir William Gowers, Dr. Heron, Dr. Payne, and Dr. Poore. Finally Dr. RADCLIFFE CROCKER moved and Sir WILLIAM GOWERS seconded:—

That the report be referred back to the committee to make it clear that Clause 2 [in the "Translation"] only applies to countries mentioned in Clause 1.

This resolution was carried.

A report, dated Nov. 9th, was received from the Committee on the Notification of Infectious Puerperal Diseases under the Public Health (London) Act, 1891, appointed on Oct. 27th. The report was as follows:—

That this committee is of opinion that, with a view to the limitation of dangerous infectious diseases, the London County Council would be acting rightly in adopting the view that the expression "puerperal fever," as contained in Section 55 (8) of the Public Health (London) Act, 1891, should be taken to include septicæmia, pyæmia, septic peritonitis, septic metritis, and other acute septic inflammations in the pelvis occurring as the direct result of childbirth.

This report was embodied in a letter which was approved and signed by the President and forwarded to the London County Council.

The President then dissolved the Comitia.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE thirty-eighth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Nov. 29th. The Commissioners present were Lord Llandaff (chairman), the Right Hon. John William Mellor, Sir George Barclay Bruce, Mr. de Bock Porter, Major-General Scott, and Mr. Robert Lewis.

The examination of Mr. REGINALD MIDDLETON occupied the whole of the sitting and the witness put in a large number of tables referring to the cost of the water from Wales and the cost of reservoirs necessary for the scheme for taking an increased supply of water from the Thames. With regard to the cost of the Welsh scheme the witness gave an estimate founded on the cost of the Manchester, Liverpool, and Birmingham supplies.

In preparing the estimates the witness calculated the cost of head works, including dam, land, compensation, and 81 miles of conduit, at the rate of £91,611 per million gallons of supply; the remaining 81 miles of aqueduct, including land and easements, to deliver 215 million gallons daily, were calculated at £64,000 per mile. The mains between the several reservoirs were estimated at prices similar to those for similar works elsewhere. The pumping machinery was charged in the same proportion to the actual quantity of water pumped from the level at which it could be delivered by gravitation from Elstree to the higher zone as is used for the Thames reservoirs scheme. The charges for pumping from the level at which water can be delivered to the service reservoirs of the companies from Elstree are charged on the amount of water which may be pumped from these levels at 30*s.* per million gallons actually pumped.

The Manchester supply from Thirlmere, with an aqueduct about 96 miles in length, is designed to give a supply at the rate of 50 million gallons a day and will, when completed, cost £4,400,000. In the case of the Welsh supply the aqueduct is about 162 miles in length and its cost will be proportionately greater. To this again must be added the cost of the service reservoirs at Elstree, the mains and connexions between that point and the service reservoirs of the companies, pumping plant, and the cost of pumping to supply, as well as, under certain conditions, the cost of filter beds.

If the Liverpool waterworks be taken for comparison it is found that the cost of the works to supply 40 million gallons daily, with an aqueduct of about 67 miles in length, will be, when completed, £3,900,000.

The estimated cost of the Elan Valley works, to deliver 75 million gallons of water daily, with an aqueduct 80 miles in length, is £6,500,000. The cost per million gallons of supply is: Thirlmere, £88,000; Vyrnwy, £97,500; Elan Valley, £89,333; average cost per million gallons of supply, £91,611. The lengths of the several aqueducts are: Thirlmere, 96 miles; Vyrnwy, 67 miles; Elan Valley, 80 miles; average length of aqueducts, 81 miles.

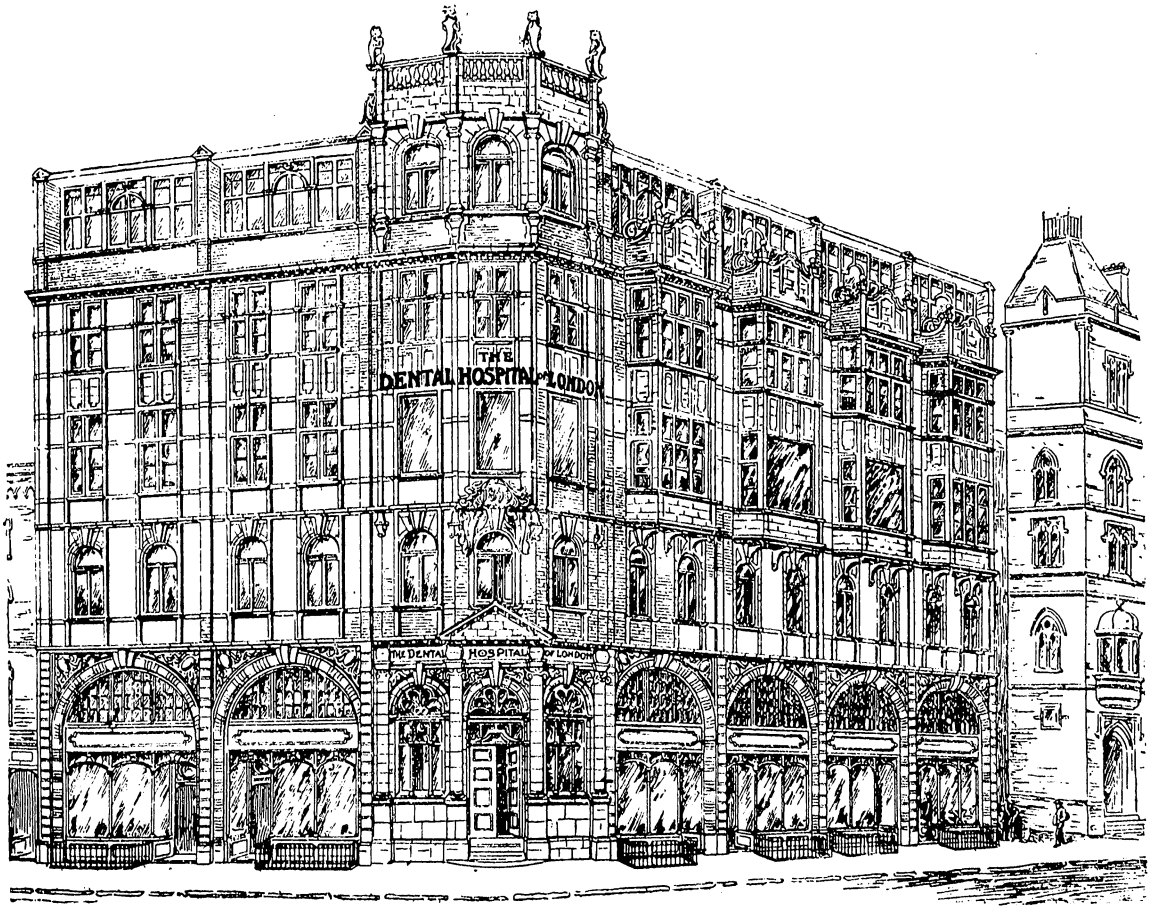
The length of the proposed aqueduct from the Yrfon to Elstree is stated to be 162 miles. It is therefore 81 miles longer than the average length of the other three aqueducts.

A very large number of tables were handed in with reference to the cost of the Thames scheme and that of the Welsh scheme. For one comparing the cost of the Thames and Welsh supply we hope to find space at an early date.

Lord ROBERT CECIL cross-examined the witness on behalf of the Hertfordshire County Council. The examination had reference to the springs and wells in Hertfordshire.

The thirty-ninth sitting of the Royal Commission was held at the Guildhall, Westminster, on Dec. 5th.

Mr. BALFOUR BROWNE, on behalf of the London County Council, cross-examined Mr. Middleton. Mr. Balfour Browne contended that it would be more costly to carry out the Staines reservoirs scheme in its entirety than to go to Wales for an adequate supply of water for London.



The next sitting of the Royal Commissioners will be held on Monday next, Dec. 12th.

A NEW infirmary to provide for the treatment of patients mentally afflicted was opened by Mr. John Penn, M.P., on Tuesday, Dec. 6th, at High-street, Lewisham, for the guardians of the poor of the Lewisham Union.

THE DENTAL HOSPITAL OF LONDON.

THE committee of management of the Dental Hospital of London, Leicester-square, are at length in a position to state that the building of the new hospital on a site adjacent to the old and very inadequate building has actually been started. Some interesting particulars of the progress of the funds for the purpose afforded several speakers at the annual dinner of the staff and past and present students of the hospital, which was held last Saturday in the Whitehall-rooms of the Hôtel Métropole, an appropriate subject of discussion. The chairman, Mr. Storer Bennett, F.R.C.S.Eng., led the way and he was followed by Mr. Trimmer, Mr. Allen Stoneham, Mr. Lloyd-Williams, and others. There was an excellent attendance, amongst those present being representatives of the staffs of the London medical schools. It appears that the efforts of the committee to acquire the new site and to secure the commencement of building operations have been considerably hampered by the requirements of parochial authorities and of the London County Council. The vestry of St. Martin's-in-the-Fields, for example, in order to improve the access to Leicester-square purchased some of the houses adjacent to those possessed by the hospital and the demolition of these rendered the whole block unsafe and the entire site had to be cleared by order of the London County Council. This means a loss to the Hospital funds of £1200 per annum and it was therefore necessary either to mortgage or abandon the site. The committee decided in favour of the former expedient and the mortgage has to be repaid in annual instalments of £1700 with interest, so that this sum of money has to be raised in addition to the money required for ordinary maintenance. The plans of the new hospital have, however, been approved by the London County Council and the Charity Commissioners having given their consent the building has now been begun. It is hoped that it will be ready for occupation in about two years' time. We are able to reproduce from the architect's drawing a sketch of the finished building. The picture to some extent illustrates the urgent need for increased accommodation to carry out this most important and valuable philanthropic work, for, as will be seen, the old hospital (to the right) though possessing a large frontage has a very small depth indeed—only 12 ft. In spite of this it was stated by Mr. Allen Stoneham in his response to the toast of "The Hospital and School," that no less than 62,512 operations were carried out last year. The arrangements of the new buildings have been very carefully considered by the medical committee with an especial view to the peculiar requirements of the institution—educational as well as philanthropic—and they believe they have secured a hospital constructed for the comfort and efficient treatment of the patient and premises wherein the student should pursue his work with success because all the advantages of modern equipment and appliances will be gained. The contemplated cost of the new buildings is £30,000, towards which a considerable amount has been subscribed, the subscription list including donations from past and present students of a magnitude which can only mean a tribute to the excellent work being done and an evidence of their conviction of the real need for larger and more efficient premises wherein to carry it on. The committee are appealing for donations towards the large amount still required.

Elevation of the building as it will appear when completed.

PUBLIC VACCINATORS AND THE NEW VACCINATION ACT.

THE PUBLIC VACCINATORS OF THE WYCOMBE UNION.

A MEETING of the public vaccinators of the Wycombe Union was held at High Wycombe on Dec. 2nd. The union is one in which there has been considerable default under the Vaccination Act for the past few years and those who were present at the meeting felt that it was important that the fee under paragraph (*a*), section 1, article 3, should be sufficient to recoup them for further domiciliary visits. The following resolutions were passed:—

1. That whereas it is to be expected that many visits will have to be paid, some of them at great distances, after due notice has been given, which, either on account of the bad health of the child or on account of its insanitary surroundings or by reason of the refusal of the parents, will not result in the performance of vaccination, it is hereby resolved that the fee under paragraph (*a*), section 1, article 3 should be 2*s.* 6*d.* instead of 1*s.*
2. That whereas the performance of vaccination under the new regulations will be a much more lengthy and troublesome operation than it was formerly, and in view of the fact that the population in the rural districts is very scattered, it is hereby resolved that the following scale of fees should be allowed under paragraph (*b*): For cases within one mile of the vaccinator's residence, 5*s.*; for cases over one mile and under three of the vaccinator's residence, 6*s.* 8*d.*; for cases three miles and over of the vaccinator's residence, 10*s.*
3. That the fee under paragraph *(c)* be accepted for vaccinations performed and inspected at the vaccinator's residence, but that vaccinations performed elsewhere, such as at a station in time of an epidemic of small-pox, should be allowed an extra fee of 2*s.* per case if more than one mile away from the vaccinator's residence.
4. That whereas the public vaccinators to the workhouse and union schools live several miles away it is hereby resolved that they should be allowed 5*s.* per case.
5. That the postage on all the forms required under the order should be paid by the guardians and that all lymph shall be supplied free of cost to public vaccinators.

It was also arranged that Mr. L. W. Reynolds, Dr. J. B. McKay, and Dr. H. J. Wheeler should act as a committee to confer with the board of guardians on these matters if required, and these three gentlemen were empowered by the meeting to arrange terms.

PUBLIC VACCINATORS AT BOOTLE (CUMBERLAND).

AT a meeting of the Bootle (Cumb.) Board of Guardians held on Nov. 26th the chief business under discussion was the consideration of the arrangements for vaccination under the new Act. The vaccination medical officers—Mr. Stoney, Mr. Hudson, and Dr. Cass—were in attendance.

The Clerk stated that in Millom district 1*s.* 6*d.* per case of vaccination was allowed, while in the Ulpha district 3*s.* per case was the fee. He would also say that the board of guardians and the medical officers were unable to agree that the fees would be fixed by the Local Government Board.

Mr. Stoney pointed out that though the minimum fee, 5*s.*, was a good fee for town work it was nothing like enough for work in the rural districts, where a practitioner might have to go twenty miles. Besides that, the vaccination medical officer had to send out notices and to pay the postage out of his own pocket. He considered that mileage should certainly be paid in addition. After a long discussion it was agreed on the motion of Mr. Lewthwaite that the fees in Mr. Stoney's district should be 5*s.* for the urban district, 11*s.* for Millom rural district, and 25*s.* for the Ulpha district, all per case.

Mr. Stoney having agreed to accept this as a temporary arrangement Dr. Cass was called before the board. He said that he wished to be paid at the mileage rate. It was, however, proposed that his fee should be 13*s.* 6*d.* for every successful case and with this arrangement Dr. Cass expressed himself satisfied. In Mr. Hudson's case it was agreed that his fee should be 10*s.* 6*d.* for every successful case and after some consideration Mr. Hudson agreed to this amount. We are glad to see that the proceedings, judging by the report in the *Whitehaven News*, were conducted without any of the acrimony and heat which unfortunately are only too common when vaccination matters are under discussion. A letter from Mr. Stoney dealing with the subject appeared in THE LANCET of Dec. 3rd and reference is also made to the matter in our leading columns of to-day.

PUBLIC VACCINATORS AT SCARBOROUGH.

At a meeting of the Scarborough Board of Guardians held on Dec. 1st letters were read from Mr. J. S. Vassalli (Scarborough), Mr. G. T. Wilkinson (Cloughton), Mr. O. Norris (Sherburn), Mr. J. T. Haworth (Filey), Dr. G. J. B. Hope (Hutton-Buscel), and Dr. M. Ranken Bow (Snainton). The writers declined to accept the minimum vaccination fees and asked the board to allow 2*s.* 6*d.* for each case under Article 3, section *a*, and 7*s.* 6*d.* for each case under sections *b* and *c*. The minimum fees allowed by the Vaccination Order, dated October, 1898, are 1*s.* under section *a*, 5*s.* under section *b*, and 7*s.* 6*d.* under section *c*. The matter was referred to the finance committee.

"A SCHOOL OF TROPICAL MEDICINE."

WE have not thought it necessary to print at length a memorandum which has been issued by the Seamen's Hospital Society with the idea of answering certain objections which exist to the projected School of Tropical Medicine, because the memorandum was not sent to us—for reasons best known to the committee of the society. We have seen a copy of it, however, and we give the gist of it in a leading article this week.

We publish below a letter which has been addressed to Mr. Michelli, the secretary of the Seamen's Hospital Society, by Sir William Broadbent in acknowledgment of the receipt of the memorandum:—

84, Brook-street, Grosvenor-square, W., Dec. 7th, 1898.

DEAR MR. MICHELLI,—You have done me the honour to send me a copy of the memorandum issued or to be issued by the committee of the Seamen's Hospital and I feel bound to make one or two observations upon it.

It is implied that because the first four of the contentions have been carefully considered by the Secretary of State for the Colonies they may be regarded as *choses jugées*. But the Secretary of State would be guided by the information laid before him, and if this information was imperfect or one-sided his approval was obtained under false pretences.

The personal matter of the injustice and discourtesy to the medical staff of the *Dreadnought* is said (par. 5) to have nothing whatever to do with the merits or demerits of the scheme. But this discourtesy entirely prevented certain aspects of the question from being brought to the notice of the Secretary of State and made the data on which he based his judgment imperfect and one-sided.

How little any conclusion formed by the committee is entitled to respect is made clear by the memorandum itself. "It may be mentioned," it says, "that the visiting staff of the *Dreadnought* have been invited to coöperate," leaving it to be understood that this invitation was part of the original scheme, whereas it was not sent till it had become an insult.

This *suggestio falsi* is aggravated by the circulation with the memorandum of a copy of Sir H. Burdett's letter from which the passage in which he states that the senior medical staff of the *Dreadnought* would form part of the teaching staff of the school is omitted. A committee capable of such a suppression of truth material to the issue and of such a suggestion of what is calculated to mislead is, in my opinion, totally unworthy of confidence.

Yours faithfully,
W. H. BROADBENT.

We have received from Mr. G. R. Turner, the surgeon to the *Dreadnought* Hospital, the following letters for publication. They complete the story told by the letters published last week and confirm our opinion that the honorary medical staff of the *Dreadnought* Hospital have been treated with marked discourtesy by the committee.

49, Green-street, Park-lane, W.,
July 19th, 1898.

DEAR SIR,—I have conferred with Drs. Curnow and Anderson on the subjects mentioned in Sir H Burdett's letter to the *Times* which by your direction was sent to me. I was astounded to hear from them that this letter was the first notice they had of the project for a school for tropical medicine in which their services and possibly mine were to be used as members of the teaching staff. Had I, a surgeon, been the only one of the visiting staff kept in ignorance of the matter I should not have supposed that any intentional discourtesy was meant, nor can I think even now that

Digitized by Google

it has been more than a blunder on the part of the Managing Committee to direct the publication of their intentions in the *Times* newspaper before conference of any kind with those so closely interested as the honorary visiting staff of the *Dreadnought* Seamen's Hospital. As a member of that senior staff mentioned by Sir H. Burdett I should like much to know the constitution of the sub-committee which reported that 78 per cent. of the cases of tropical disease go to the Branch Hospital; by whom was it decided what cases were tropical and what not; and whether this report may be inspected and shown to be accurate and true (a very necessary proceeding before asking the public to subscribe to the erection of buildings and the attempted formation of a school in a very out-of-the-way and inaccessible situation); by whom were the already elaborate plans for this proposed school drawn up; and did their author or authors know that the visiting staff of the *Dreadnought* Hospital were in absolute ignorance that such a scheme was on foot?

I have written thus freely because as a surgeon these matters do not nearly concern me, and I cannot help feeling that my medical colleagues have been treated with a marked lack of the ordinary consideration to which all of us honorary officers are entitled, and I trust that the Managing Committee will be able to give us some explanation.

Believe me, yours faithfully,
(Signed) G. R. TURNER.

To the Chairman of the Committee,
Seamen's Hospital, Greenwich.

3, Crosby-square, Bishopsgate, E.C.,
July 20th, 1898.

SEAMEN'S HOSPITAL.

DEAR SIR,—I write a line to acknowledge the receipt of your letter of July 19th, 1898.

I am sorry to learn that the senior medical staff of the *Dreadnought* Hospital take exception to portions of Sir Henry Burdett's letter relating to the proposed establishment at the Branch Hospital of a school for the study of tropical diseases which was published in the *Times* of July 11th.

The questions asked by your letter are rather for the Committee of Management than for me personally as chairman to reply to. I will take care that your letter is brought before the committee at their next meeting.

I am, dear Sirs, yours faithfully,
(Signed) PERCEVAL A. NAIRNE.

G. R. Turner, Esq., F.R.C.S., 49, Green-street, Park-lane, W.

49, Green-street, Park-lane, W.,
July 21st, 1898.

DEAR SIR,—Thank you for your letter of July 20th. The senior medical staff of the *Dreadnought* Hospital—I believe I may speak for us all—take exception to the elaboration and publication of a scheme for a school in which it is stated they will teach before any of them had heard a word on the matter. It is not, I think you will agree with me, customary or considerate to make statements about the coöperation of honorary officers in work the existence of which they know nothing about. This Sir H. Burdett has done by the direction of the Managing Committee and it is against this that I most vigorously protest. It is not, I will only say, usual for managing committees to ignore the honorary staff as we have been ignored. It looks, although I can hardly believe it, that we have been purposely kept in the dark.—Believe me, yours faithfully,
(Signed) G. R. TURNER.

Perceval A. Nairne, Esq.

Dreadnought Seamen's Hospital, Greenwich, S.E.,
Sept. 15th, 1898.

DEAR SIR,—Your letters to the chairman of July 19th and 21st have been laid before my Board.

The committee feel that their relations with the medical staff in the past are a sufficient answer to the suggestion that any discourtesy or want of consideration towards them in connexion with the society's reply to the Secretary of State's proposal for the establishment by the society of a school for the study of tropical diseases was intended.

The committee regret that any expression in Sir Henry Burdett's letter published in the *Times* of July 11th should appear to you and to some of your colleagues to have represented that you and they had engaged to take part in the educational work of the school. Sir Henry Burdett (with the committee) probably felt no doubt that the educational work would in the main be taken charge of by the medical staff of the society's hospitals, but the committee do not read his letter as a pledge that each member of the staff would join in the educational work.

The committee have read with much regret the joint letter of Dr. Curnow, Dr. Anderson and yourself, published in the *Times* of July 20th, and in some of the medical papers a few days later, which they feel must tend to injure the success of the project into which the committee have entered at the invitation of the Secretary of State. They will be glad to know whether they are to infer from it that the writers have renounced all connexion with the proposed school and upon this point they ask for a definite reply at an early date. Yours faithfullly,

P. MICHELLI, Secretary.

G. Robertson Turner, Esq., F.R.C.S.,
49, Green-street, Park-lane, W.

A FIFTH REPORT TO THE REGISTERED PRACTITIONERS OF ENGLAND AND WALES.

SINCE my last report to the Registered Practitioner of England and Wales published in the medical journals of May 14th of this year another session of the Council has taken place. I am therefore in a position to report definitely concerning certain matters which were at issue on the date mentioned. These matters are as follows:—

I. The inspection of documents.
II. The case of the late Mr. Herbert K. Hunter, L.S.A.
III. The Midwives Bill question.
IV. The medical aid question.
V. The question of reciprocity in foreign practice.
VI. The amendment of the Medical Acts and the relation thereto of the Council's work in regard to unqualified practice by (*a*) individuals—i.e., quacks, and by (*b*) companies.
VII. The responsibility of the Council for the character of the higher registrable qualifications.

I. *The inspection of documents.*—It will be remembered that immediately upon his election on April 7th, 1898, the President gave orders that I should not be allowed to see any documents the property of the Council, although up to the date named I had enjoyed the customary rights of a member of the Council. Unfortunately for the furtherance of business this act of the President was supported by a motion carried in the Council at the May Session, 1898, by Dr. Glover and Dr. Bruce and the matter was further complicated by the Council accepting on the proposal of Dr. MacAlister Dr. Glover's motion as a Standing Order. With the view of restoring the rights of members of the Council and thereby defending your interests I took the advice of Mr. Hempson and the opinion of Mr. Henry Buckley, Q.C., on the matter. Mr. Buckley's opinion briefly stated amounted to the following propositions:—That the case of the King *v.* the Merchant Taylors' Company which had been cited to the Council did not apply, as indeed I had already shown, to the case of members of the Council and also, as Mr. Hempson had advised me, was directly negatived by the case of Byrne *v.* the South Wales Coal Company; that under these circumstances my position was clearly defined and good and supported by the dicta of the judges in the first case mentioned; that, however, the case was wholly prejudiced by the action of the Council in making Dr. Glover's motion into a Standing Order; that it was legally possible for the Council by such Order to hamper its work and the opportunities of its members in any way provided that no member could show damage or serious obstruction to his work to result from such hindrance; that it would be advisable to move at the next session for the production of documents and that if these were refused I could then apply to the High Courts for a remedy. I therefore moved at the recent session several motions for the production of various sets of papers. Although opposed as strongly as possible by Dr. MacAlister, the chairman of the Business Committee, and the President, the Council supported me by majorities amounting to over three-fourths of the Council. The discussions which preceded these votes created such an unfavourable impression that several members of the Council

Digitized by Google

insisted that since every member had a prescriptive right to see the documents no delay should occur in the latter being produced for their inspection. More than this, later in the session a motion was proposed by Sir Richard Thorne and carried to the effect that, inasmuch as the operation of Dr. MacAlister's Standing Order of the previous session was "not altogether satisfactory" the Executive Committee were directed to report as to the best means of facilitating the examination of documents by members of the Council. This resolution of Sir Richard Thorne was carried *nem. con.*, and although such a vote was a very striking commentary on the events of the previous session the resolution contained one error of procedure which will require to be removed later—namely, that leave must be asked of someone or of the Council before documents can be produced by the Registrar. This, of course, conveys with it the assumption that some members of the Council have an authority over other members of the Council, but such a position is contradictory to the Medical Acts under which all the members of the Council have equal rights and no statutory authority can be delegated to any official whatsoever. The profession must clearly understand that it is not possible for the Direct Representatives to carry out their work properly until these illegal restrictions are fully removed, but at least it is very satisfactory to note that the proceedings of this last session have to a large extent neutralised the injury inflicted six months ago.

II. *The case of the late Mr. H. K. Hunter, L.S.A.*—The case of this gentleman who unfortunately died after his conviction for calling himself a physician is one of vital importance. It was one (in which a registered practitioner was prosecuted by the Council under Section 40 of the Medical Act for calling himself a physician) which excited much attention at the time—i.e., April, 1898—and I was especially attacked in the medical journals as having sanctioned this particular prosecution and as being, in fact, responsible for it as a member of the Council though a Direct Representative of the profession. The only constitutional course open to me was to raise the matter in the recent session of the Council, but discussion of it being refused me by a narrow majority I have no option now but to clear myself before the profession and show that not only was I not responsible but that also the Council itself was not responsible and that the prosecution in question was wholly unauthorised and conducted upon lines which have never been the subject of discussion in the Council at all. Mr. Hunter was an L.S.A. and a registered medical practitioner. He was complained of to the Council for using the title of M.D., he only possessing the M.D. of Philadelphia. On being warned that he was doing an illegal act he thereupon ceased to use the M.D. However, the Penal Cases Committee reported his case to the Council as one suitable for prosecution under Section 40 of the Medical Act and his conduct was described to the Council as that of an unregistered person practising under an American M.D. degree. The Council on this information ordered that a summons should be issued under Section 40 of the Medical Act to restrain, as they believed, an unregistered person from practising under the cover of an American diploma. This decision was come to at the November session, 1897. The profession will now readily understand with what feelings I read in the *Times* in April, 1898, the account of the hearing of the summons from which it appeared that Mr. Hunter was a *registered* practitioner holding an L.S.A. diploma and that he was prosecuted not for calling himself an M.D. but for putting upon his bill-heads the word "physician," that he was convicted and fined £5, and that he had lodged an appeal against the conviction. This was the first stage of this matter and it will be seen that Mr. Hunter was prosecuted on a charge which had never been discussed by the Council and had never been authorised by the Council. At the May session, 1898, soon after these proceedings were made public, Mr. Brown and myself raised the question to draw attention to the procedure of the Penal Cases Committee and of the law officers and to inquire by whose authority this prosecution had been initiated. The President appealed to Mr. Brown to withdraw his motion on the ground that the case was still *sub judice*. Unfortunately, Mr. Brown assented, though on the understanding that the matter would be brought forward at the next, the recently completed session. Not long after the May session Mr. Hunter died and the Apothecaries' Society determined to prosecute the appeal in his stead. It being impossible under the recent Standing Order of the Council forbidding inspection of documents to find out what steps were being taken in this matter in the name of the Council until the session began on Nov. 22nd, Mr. Brown and I on that date moved for the documents in the case to be produced and, as just stated, we carried that motion in the face of a strenuous opposition offered by the President, the chairman of the Penal Cases Committee, by Dr. MacAlister, by Dr. Heron Watson, and by Mr. Carter. Gathering from the perusal of the surrendered papers that the appeal was being resisted by someone using the authority of the Council I asked the Registrar who were the parties in the appeal case, but neither he nor the President nor the Penal Cases Committee nor any of the Members of the Council were in the possession of any such information. On my pressing the matter the President agreed to write and find out what was the position of the Council in the appeal case immediately pending. The legal assessor informed the President that the General Medical Council was resisting the appeal on the ground (as he had already told the High Court) that Mr. Hunter had no right to call himself a physician. It follows therefore that not only the original prosecution but also the resistance to the appeal have been instituted without the Council being afforded the slightest opportunity of discussing the merits of the case or authorising action upon it. This is the first issue in the Hunter case—namely, the utterly unconstitutional nature of the procedure—and this issue I endeavoured to raise on three separate occasions during the last session but was ultimately defeated though by a bare majority. The other issue which should be called the main issue—namely, whether Mr. Hunter as an L.S.A. registered under the Act of 1886 had the right to call himself a physician—is one about which I have no doubt whatever and which it is easy to show is not governed (as was alleged before the magistrates) by the case of Regina *versus* Baker. This question of the merits of the case I will discuss on a subsequent occasion.

III. *The Midwives Bill question.*—The matter of legislation for midwives came up before the recent session of the Council and a small committee was reappointed to watch the introduction of any further legislation as it seemed likely that such action might be taken by the Government. Further, a few additions were carried in the Council to the former principles which were laid down by the Council in the May session of the present year and which principles it will be remembered were fully adopted by the Duke of Devonshire, the Lord President of the Privy Council.

IV. *The medical aid question.*—As will be seen by the published reports of the Council's session the committee which has this matter in charge has only published an interim report because it has been arranged to hold a conference with the officials of the reputable friendly societies in order to satisfy themselves of the precise position of such associations in relation to the medical profession. Such conference cannot take place before early in 1899 and consequently the committee in question can only publish their full report at the next, the May, session of the Council. Greatly regretting as I do the delay in the Council taking up a definite attitude on this important matter there is no possibility of altering the procedure that has been entered upon.

V. *The question of reciprocity and foreign practice.*—In the May session I brought up this matter and showed that the document issued by the Council as an authoritative one on the question of reciprocity in foreign practice was not in accordance with the Medical Acts. After some discussion it was referred back to the Executive Committee for amendment and report. When, however, in the recent session their report was approached on the programme the President suggested that it was a matter which did not press and could be postponed for six months, with which of course I agreed and especially as in its amended form the document is still in my opinion misleading.

VI. *Amendment of the Medical Acts.*—The relation of the work of the Council in regard to unqualified practice received considerable attention this session and very distinct advance was made in more than one direction. The prevention of unqualified practice is necessarily to be considered under two headings, according as to whether (*a*) it is carried on by an individual or (*b*) by a company. As regards the individual the singularly gross case of misprision of justice in the magistrates' treatment of the case prosecuted at Norwich by the Medical Defence Union came before the Council which, however, unfortunately could not intervene inasmuch as the magistrates stated that they arrived at their decision on the point of fact and not of law. Upon this I drew the attention of the Council to the necessity of

Digitized by Google

meeting such constructive evasion of the law by an amendment of the Medical Act and obtained from Mr. Muir Mackenzie a reconsideration of his former adverse opinion on this subject. The question of the infringement of the Medical Acts by companies is another point and is being dealt with by a special committee consisting of the President, Mr. Tomes, and myself. Proposals which were subsequently approved by the Council have been furnished to the Government whereby it is to be hoped that the companies constructed for the sole purpose of evading the clauses of the Medical Act will be extinguished.

VII. *The responsibility of the Council for the higher qualifications.*—In connexion with the matter of higher qualifications I gave notice at the recent session that I would draw attention to the fact that a memorial had been presented to the Council by certain members of a medical corporation complaining in specific terms of reprehensible insufficiency of the examination for the Fellowship of the corporation. As a matter of fact this memorial which had been addressed to the Council had never reached the Council because it was returned by the President to the complainants on the ground that the Council had nothing to do with any superintendence of, or was in any way responsible for, the status of examinations for higher qualifications. The matter being placed in my hands by the persons aggrieved in order that it should come before the Council I gave notice of the motion alluded to, but when it came on for discussion the President ruled it out of order on the same ground as that upon which he had returned the memorial—namely, that the question involved was not within the purview of the Council. There are two points included in this matter: the first is the act of the President in taking upon himself to reject a memorial addressed not to him but to the Council. The President has, I submit, no right to debar memorialists from approaching the Council, and, in fact, there is no restriction on memorials except that they must not relate to more than one subject. I did not bring up before the Council the question of the President's action because, it being the end of the session, I was anxious to obtain a hearing for the very important question raised by the memorial—namely, an alleged insufficiency of the examination which was that for the Fellowship of the Faculty of Physicians and Surgeons of Glasgow. In this, however, I was disappointed, because the President ruled the motion out of order and the whole matter was thus once more suppressed so far as the General Medical Council was concerned. This ruling of the President was evidently given without reference to the sections of the Medical Act of 1858 which deal with this subject and specifically with the examination for the Fellowship of the Faculty of Physicians and Surgeons of Glasgow. I therefore at once gave notice that I would raise the question at the next session—namely, in May, 1899.

VICTOR HORSLEY.

Dec. 5th, 1898.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6638 births and 4108 deaths were registered during the week ending Dec. 3rd. The annual rate of mortality in these towns, which had been 17·0 and 17·4 per 1000 in the two preceding weeks, further rose last week to 19·1. In London the rate was 18·2 per 1000, while it averaged 19·7 in the thirty-two provincial towns. The lowest rates in these towns were 12·4 in Burnley, 13·5 in Halifax, 15·3 in Cardiff, and 15·9 in Sunderland; the highest rates were 23·4 in Derby, 24·2 in Salford, 24·8 in Newcastle-upon-Tyne, and 27·8 in Wolverhampton. The 4108 deaths included 426 which were referred to the principal zymotic diseases, against 371 and 364 in the two preceding weeks; of these 108 resulted from diphtheria, 87 from measles, 71 from "fever" (principally enteric), 71 from whooping-cough, 49 from diarrhœa, and 40 from scarlet fever. The lowest death-rates from these diseases were recorded in Plymouth, Burnley, Halifax, and Gateshead, and the highest rates in Preston, Blackburn, Salford, and Swansea. The greatest mortality from measles occurred in West Ham, Portsmouth, Swansea, Bolton, and Newcastle-upon-Tyne; from whooping-cough in Swansea and Preston; and from "fever" in Wolverhampton, Blackburn, and Sheffield. The mortality from scarlet fever showed no marked excess in any of the large towns. The 108 deaths from diphtheria included 43 in London, 15 in Leeds, 9 in Swansea, 7 in West Ham, 4 in Blackburn, and 4 in Sheffield. No fatal case of small-pox was registered during the week under notice, either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 3142, against 3188, 3259, and 3162 on the three preceding Saturdays; 264 new cases were admitted during the week, against 340, 319, and 234 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 285 and 280 in the two preceding weeks, rose again last week to 340, but were 71 below the corrected average. The causes of 62, or 1·5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Oldham, Sunderland, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Cardiff, Birmingham, Liverpool, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the four preceding weeks from 18·9 to 19·7 per 1000, further rose to 21·0 during the week ending Dec. 3rd, and exceeded by 1·9 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·3 in Greenock, and 18·7 in Perth, to 21·5 in Edinburgh and 22·0 in Glasgow. The 632 deaths in these towns included 21 which were referred to whooping-cough, 19 to measles, 17 to diarrhœa, 11 to diphtheria, 10 to "fever," and 5 to scarlet fever. In all, 83 deaths resulted from these principal zymotic diseases, against 70 and 73 in the two preceding weeks. These 83 deaths were equal to an annual rate of 2·8 per 1000, which was 0·8 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 9 and 19 in the two preceding weeks, further rose to 21 last week, of which 15 occurred in Glasgow. The 19 deaths from measles also showed a further increase upon recent weekly numbers, and included 9 in Edinburgh, 6 in Glasgow, and 3 in Dundee. The fatal cases of diphtheria, which had been 11 and 5 in the two preceding weeks, rose again to 11 last week, of which 7 occurred in Glasgow and 2 in Paisley. The 10 deaths referred to different forms of "fever" were within one of the number recorded in the preceding week, and included 6 in Glasgow and 2 in Edinburgh. The deaths from diseases of the respiratory organs in these towns, which had been 130 and 128 in the two preceding weeks, rose again to 147 last week, and were 22 above the number in the corresponding period of last year. The causes of 51, or more than 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·7 and 31·0 per 1000 in the two preceding weeks, further rose to 31·6 during the week ending Dec. 3rd. During the past four weeks the death-rate in the city has averaged 30·1 per 1000, the rate during the same period being 17·0 in London and 20·6 in Edinburgh. The 212 deaths registered in Dublin during the week under notice showed an increase of 4 upon the number in the preceding week, and included 11 which resulted from the principal zymotic diseases, against 9 and 17 in the two preceding weeks; of these, 4 were referred to scarlet fever, 3 to whooping-cough, 2 to "fever," 1 to measles, 1 to diphtheria, and not one either to small-pox or diarrhœa. These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 1·7 in London and 2·5 in Edinburgh. The 4 fatal cases of scarlet fever corresponded with the number recorded in the preceding week. The deaths from whooping-cough, which had been 2 and 5 in the two preceding weeks, declined to 3 last week. The 2 deaths referred to "fever" corresponded with the number in the preceding week. The 212 deaths in Dublin last week included 34 of infants under one year of age and 46 of persons aged upwards of sixty years; the deaths of infants showed an increase, while those of elderly persons were considerably below the number recorded in the preceding week. Six

Digitized by Google

inquest cases and 2 deaths from violence were registered; and 78, or more than a third, of the deaths occurred in public institutions. The causes of 12, or nearly 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE under-mentioned Staff Surgeons have been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet:—Alexander John James Johnston and James O'Brien Williams.

ARMY MEDICAL STAFF.

Surgeon-General Albert A. Gore is placed on retired pay.

ROYAL ARMY MEDICAL CORPS.

Colonel Fraser succeeds Colonel Scott as Principal Medical Officer, North-Western District, Chester. The employment of Major Brazier-Creagh with the Pekin Syndicate has been sanctioned. Lieutenant-Colonel Lloyd, V.C., has been appointed to the Medical Charge of the Burma-China Boundary Commission. Major Cusack is under orders to proceed to India. Major Russell and Major Stoney embark in the *Dunera* for Bombay.

VOLUNTEER CORPS.

Artillery: 1st Dorsetshire (Southern Division, Royal Artillery: Surgeon-Captain D. T. Key, from the 1st City of London Volunteer Artillery (Eastern Division, Royal Artillery), to be Surgeon-Captain. 1st Glamorganshire: Surgeon-Lieutenant-Colonel C. Pegge resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement. *Rifle:* 8th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Captain R. Kirk to be Surgeon-Major. 2nd Volunteer Battalion the Northumberland Fusiliers: Surgeon-Lieutenant-Colonel H. F. Hurst resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the battalion on his retirement. 3rd (Dumfries) Volunteer Battalion the King's Own Scottish Borderers: Honorary Assistant Surgeon W. Kay resigns his commission and is permitted to continue to wear the uniform of the battalion on his retirement. 3rd Lanarkshire: Andrew Stewart Tindal to be Surgeon-Lieutenant. 1st (Oxford University) Volunteer Battalion the Oxfordshire Light Infantry: Walter Tyrrell Brooks to be Surgeon-Lieutenant. 1st Nottinghamshire (Robin Hood): Surgeon-Lieutenant Robert Plenderleith Shearer resigns his commission and is appointed Second Lieutenant (Supernumerary). 1st Wiltshire: Penrose John Barcroft to be Surgeon-Lieutenant. 3rd (The Blythswood) Volunteer Battalion the Highland Light Infantry: Surgeon-Captain J. S. McConville resigns his commission. 2nd Volunteer Battalion the Gordon Highlanders: Surgeon-Major Sir J. Reid, Bart., K.C.B., resigns his commission and is granted the rank of Surgeon-Lieutenant-Colonel, with permission to continue to wear the uniform of the battalion on his retirement. 26th Middlesex (Cyclist): Percy James Edmunds to be Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF CORPS.

The Aberdeen Company: Ashley Watson Mackintosh to be Surgeon-Lieutenant. The Woolwich Company: Surgeon-Captain P. O. Haynes resigns his commission.

THE HYGIENE OF BARRACK-ROOMS.

In his third and concluding Harben Lecture Sir Richard Thorne was able to say that administrative measures in this country have led to a saving of no less than 60 lives out of every 100 which at many age periods were formerly sacrificed to phthisis pulmonalis. This is truly the record of a magnificent achievement—a triumph of science over disease of which sanitarians may well be proud; but at the same time, although much has been accomplished, there still remains much to be done before the workers in this particular field can fold their hands and declare themselves satisfied with their labours. In the army, for instance, the victims of preventable disease are still unduly numerous. *A priori* it might be thought that a body of sound young men—picked lives, well fed, well lodged, well clothed, and by no means excessively worked—should be practically free from tuberculous disorders, but, unfortunately, such is far from being the case. It is, happily, true that of late years the mortality from phthisis pulmonalis and the other allied affections which, taken together, are included under the term "tuberculosis," has enormously diminished, but it is still too high, while the loss by invaliding under the same heading is also lamentably great. The causes which favour the onset of tuberculosis among soldiers may be complex, but enough is now known of the intimate nature of the infecting agent to warrant the belief that its virulence could be diminished by intelligently-applied prophylactic measures. Whatever may be the case as regards the civil population in general, the stamping out of tuberculosis in the army should be perfectly feasible, and surely the consummation is highly to be desired, were it merely for financial reasons. In France, where destructive lung disease is at least as deadly as it is with us, the whole subject of tuberculosis has recently been surveyed in a masterly manner by Professor Grancher, whose report embodies the views of the most advanced hygienists in the country. The condition of things prevalent in the French army is eloquently described. We do not go so far as to apply the Horatian maxim *mutato nomine de te fabula narratur*, but the following extract from M. Grancher's academic work is well worth the notice of our own army authorities, military as well as medical.

> Whatever may be the part played by infection in the dissemination of tuberculosis among soldiers, the fact remains that the disease exists and, what is more, that it exists to a considerable extent. This being universally admitted it is unnecessary to advance further proof. But what is there done by way of combating the evil? In a barrack-room the first half-hour after reveille is devoted to dressing, to perfunctory bed-making, to floor sweeping, and to breakfast. These operations go on simultaneously, so the men have to swallow their coffee and rolls in a dust-laden atmosphere. Spittoons are scarce or entirely deficient, and coughers, if there are any, spit where they choose. The medical officer does not, and cannot, interfere; the internal economy of the room, hygiene included, belongs to the commanding officer—that is, to the captain commanding the troop or company. But is the latter aware of the fact that bacilli-laden dust is dangerous? Or, if he should be aware of it, does he take the necessary steps? No, it must be admitted that he does nothing; and here it is that we find the weak link in the chain. The barrack-room is choked with dust, the dust contains the broken-up sputa; hence arises the infection. Of course all spitting outside spittoons should be sternly forbidden under pain of severe punishment. Spittoons should always be kept moist and should also be fixed breast-high. Their cleansing and thorough disinfection should be a daily task. Finally, sweeping of floors is a fault; floors should be treated with coal-tar or paraffin and cleansed by means of a damp cloth. Now, according to existing regulations the medical officer can do nothing, has no right to exercise supervision. The combatant officer alone—be he captain, colonel, or commandant—can see to the execution of sanitary hygiene. It is therefore necessary that combatant officers should be taught to appreciate the dangers to which their negligence exposes the health of the men for whose well-being they are responsible. The lessons in practical hygiene which are given at Saint-Cyr, at Saint-Maixent, and at Fontainebleau ought to be more complete and probably more accurate. But lessons of this description could alone never suffice, and I hereby appeal to all army medical officers to take advantage of their intimate associations with their combatant brethren, so that all officers and men alike may become imbued with the same sanitary convictions by which they themselves are animated. In propagating true sanitary notions far more good is likely to accrue from judicious hints dropped at the mess than from the most elaborate of official reports. The only way to ensure progress in hygiene is by awakening the consciences of those in authority to a recognition of the fact that they it is who are responsible for the health of their men. Thus alone is it possible to create new manners and customs amidst the combatant hierarchy—manners and customs which will be dominated by a wholesome dread of tuberculosis and of its active principle.

A FRENCH MILITARY SURGEON'S VIEW OF THE SEQUELÆ OF INFLUENZA.

Surgeon-Major J. Marty's short paper on the Cerebro-spinal Complications of Influenza which occupies the leading position in Duplay's *Archives Générales de Médecine* for November is chiefly remarkable for its wealth of reference, but although upwards of 50 authorities—French, German, and Swiss—are cited there is no mention made of the works of British or American writers. The greater part of the paper is occupied by the cases of 8 soldiers, which are related at length with a considerable amount of detail; 6 of these cases ended fatally, but in 2 only were necropsies permitted. Surgeon-Major Marty's chief contention seems to be that the occurrence of cerebro-spinal symptoms after influenza depends upon the intensity of the original "intoxication." His experience extends over three separate epidemics. In the first, the intoxication being mild, there were no cerebro-spinal sequelæ. In the second, the intoxication being graver, certain symptoms of "pseudo-meningitis" presented themselves subsequently. In the third the intoxication carried all before it and the ensuing "meningeal accidents" were invariably fatal. It may be interesting to note that the average stature of the men treated was 5 ft. 3 in. and their chest measurement 33·4 in. They all belonged to a line regiment.

THE PRINCIPAL MEDICAL OFFICER OF HER MAJESTY'S FORCES IN INDIA.

It has been alleged that an attempt has been made to induce the home authorities to sanction an arrangement by which Surgeon-General Harvey would combine the duties of direction of the Indian Medical Service with those of Principal Medical Officer of Her Majesty's forces in India. As we have already announced, however, the successor to Surgeon-General Gore, who vacates his appointment this month, will be Surgeon-General Taylor, C.B., and we do not believe that any rumours to the contrary have any foundation in fact.

THE VICTORIA CROSS.

The Queen has been graciously pleased to signify her intention to confer the decoration of the Victoria Cross on Surgeon William Job Maillard, M.D. Lond., Royal Navy, whose claims have been submitted for Her Majesty's approval, for his conspicuous bravery during the outbreak at Candia on Sept. 6th, 1898. We refer in another column to the splendid circumstances in which Surgeon Maillard's cross was won.

COLONEL F. B. SCOTT, R.A.M.C.

Colonel F. B. Scott, C.M.G., who has been placed on the retired list and has consequently vacated his appointment at Chester, joined the Army in October, 1862, and reached his present rank in 1892. He served in the Zulu war, 1879, when he was mentioned in despatches, and in the Egyptian campaign of 1882.

DEATHS IN THE SERVICES.

Lieutenant-Colonel Thomas Mayne, I.M.S., at Melbourne, in his fiftieth year. He entered the Indian Army in 1872 and was subsequently in charge of the medical department of the 24th Madras Infantry. He died while he was on his way home for the benefit of his health, being landed at Melbourne.

Correspondence.

"Audi alteram partem."

INSTRUCTION IN TROPICAL MEDICINE.

To the Editors of THE LANCET.

SIRS,—In referring to the subject of a proposed School of Tropical Medicine in your issue of Nov. 26th you remark that laboratories already exist on the Victoria Embankment at Chelsea and at certain metropolitan schools. A "Colonial Physician," writing in the *Daily Chronicle* (Nov. 29th), supports the suggestion of a new laboratory by stating that the existing institutions exist for "a variety of quite different uses." I should esteem it a great favour if you would allow me to state the case on behalf of the bacteriological department of King's College, London. I wish also to make some suggestions which I venture to think may possibly have the effect of promoting the object which Mr. Chamberlain has in view.

As regards the laboratories at King's College let me say most emphatically that they differ very materially from those attached to some of our metropolitan medical schools. Twelve years ago these laboratories were founded and equipped for *teaching and research*. They were opened to all comers and special facilities were granted to colonial and foreign practitioners both for obtaining instruction and for carrying on original research. More than 1000 qualified medical practitioners, many of them holding high positions in the colonial, naval, Indian, and army medical services, have entered for instruction in the laboratory. The list of registered names includes those of practitioners and medical officers from Egypt, West Coast of Africa, Uganda, the Cape, British Guiana, Jamaica, Trinidad, Straits Settlements, India, Ceylon, China, Japan, Queensland, New South Wales, Canada, New York State, Michigan, Ohio, Missouri, Indiana, California, Florida, Chili, and Buenos Ayres. Several workers in the laboratory have been specially trained with a view to combating plague, cholera, yellow fever, madura disease, actinomycosis, cattle plague, pleuro-pneumonia, and other diseases prevalent in our colonies and in foreign countries. The Colonial and War Offices have recognised the laboratories by granting leave of absence in order that their officers might be trained in King's College.

The course of instruction consists of (1) lectures and practical instruction in all that relates to the knowledge which we at present possess of the causation and prevention of diseases of man and animals attributed to bacteria and other micro-parasites; (2) Advanced technical instruction in the methods of original research, thereby encouraging further researches in the colonies by competent observers. A thorough knowledge of these diseases cannot be imparted in a small clinical laboratory attached for convenience to the wards of a hospital. In the first place, there would be no opportunity for learning anything about the epidemic diseases of animals. It will at once be admitted that the services of colonial health officers and colonial practitioners would be of increased value if they were qualified (especially in the absence of any veterinary surgeon, or by coöperation with them) to advise upon the best means of stamping out tuberculosis, actinomycosis, cattle plague, pleuro-pneumonia, surra, Loodiana disease, &c., and also if they were competent to undertake original researches in connexion with diseases of animals, especially those communicable to man. In the second place, I would point out that cases of leprosy, yellow fever, cholera, plague, madura disease, and many other tropical diseases are very rarely imported to England, and therefore instruction at the bedside, supplemented by examination in a clinical laboratory would be very irregular and inadequate. For training students in these diseases reliance must be mainly placed upon the pathological and bacteriological investigation of morbid specimens and materials supplied from the colonies and the study of cultivations. To collect such material requires time, and to constantly carry on cultivations necessitates a large, well-equipped laboratory and a well-trained staff. The teachers should be ready at all times to give instruction and, indeed, willing to practically devote the whole of their time to teaching and research. Such a laboratory can only be provided and maintained at very great cost, and the establishment of a new laboratory on this scale would only provide for work for which provision has already been made at King's College and the Institute of Preventive Medicine. It would not supply any want, but it would enter into competition more especially with the teaching at King's College and thus undermine the work which has been carried on for twelve years. The effects of this would be severely felt.

Mr. Chamberlain's object being the advancement of the education of colonial practitioners and the control of tropical diseases, let me point out how such an admirable object can be made to receive, as it should receive, the support of all. I would venture to make suggestions which are based upon a long experience of the needs of colonial practitioners. These suggestions I will embody in the form of regulations for admission to the colonial service.

All candidates for colonial medical appointments should be required to attend and be "signed up" for the following: 1. A special course of clinical instruction in tropical medicine. This course might be given at the Seamen's Hospital and in coöperation with the metropolitan hospitals. An arrangement might be made with the metropolitan hospitals by which candidates for the colonial service were granted a circular ticket giving them the privilege of being shown in the wards any cases of interests to colonial practitioners. 2. A course of lectures on tropical medicine and hygiene, delivered at the proposed School of Tropical Medicine and the Seamen's Hospital or any other medical school recognised by the Colonial Office as providing adequate training in this subject. 3. Lectures and practical instruction for not less than six weeks in a bacteriological laboratory or institute which is recognised by the Colonial Office as fully equipped with the materials and teaching staff necessary for giving the instruction required.

I would like to add another suggestion. Those already holding appointments in the colonial service and those engaged in private practice in the colonies would derive very great benefit if they were to take advantage of these lectures and practical studies and thus keep themselves in touch with the most recent views and with current research. Encouragement might be given to those on leave from the colonies by the creation of colonial scholarships or studentships entitling the holders to free attendance on the same course of instruction demanded from candidates for the colonial service.

I am, Sirs, yours faithfully,

EDGAR M. CROOKSHANK, M.B. Lond

King's College, London, Dec. 5th, 1898.

"THE 'OPEN-AIR' TREATMENT OF TUBERCULOSIS."

To the Editors of THE LANCET.

SIRS,—As one who has for over forty years preached and practised the gospel of pure air and plenty of it night and day, summer and winter, for the treatment and prevention of respiratory maladies, especially pulmonary tuberculosis, I have felt great interest in the movement of professional opinion in this direction so marked of late and am tempted to ask you to grant me a little of your space to comment thereon.

It was about the middle of the fifties, at a time when the dismal doctrine of inheritance held sway in this country and infection was not accepted, that I first saw light and soon after found salvation by placing my faith on the *vis medicatrix naturæ* as exemplified in the uniformly successful result of the common treatment of a simple fracture. Many considerations led me to this attitude of mind, but among the chief of them was the occurrence of cases of recovery after practitioners had despaired and when patients had become reckless, such as the well-known duck-shooter mentioned by Stokes. Although for many years I recommended not only the various drugs but also many of the climates, the altitudes, and the latitudes which from time to time were advocated by persons who apparently had enjoyed some special experience, yet in the end it came about that I had to lose faith in drugs of all sorts and to conclude that as to climate, when taken into account together with other conditions of life, the people of these islands are as well off as those of any other land, and that only for those few who enjoyed travel and could afford to indulge themselves freely was there an advantage to be gained by so moving about as to secure in all parts of the year the best season. For the vast majority such life of the swallow is out of the question, and I will say no more on that subject. The principle upon which I had to rely, then, being to secure for the sick all the conditions which make for health in the healthy, and to protect against all the adverse ones, as a splint protects by securing rest, rich and varied foods within the limits of appetite and digestion were enjoined, and as much functional exercise as could be borne, as well as pure air in abundance, which, however essential, is not the whole matter.

The "open-air treatment," as it is called, I therefore hail with pleasure and am glad to note that it must when rightly apprehended finish off the remaining bogies about "draughts and chills." There are two lessons, as it seems to me, which may be learned from the perusal of the recent papers on this subject which are of equal or even greater importance than the establishment of sanatoria, valuable as I admit they may be for a certain proportion of cases and for certain classes.

The first of these to which I would call attention is the adoption of the best known modes of life as approved by the experience of special sanatoria by a person of moderate means in his own home. The number of persons who might adopt such a mode of life is, I think, much larger than of those who could or would go to a sanatorium in this country or abroad. I have noticed of late years a marked change in the mental attitude of patients affected with this malady. Whereas in the days when the doctrine of heredity held sway it was difficult to induce a patient to face the facts and almost as difficult for the medical man to be frank, now a very large proportion of them will bear being told the truth and like it. These may, if carefully instructed and moderately supervised, be trusted to carry out at home practicable measures for their "open-air treatment," and this on a balance of considerations with at least as much hope of recovery as at any sanatorium here or abroad.

The other lesson is that the measures upon which practically everyone now relies for the cure of the malady are just those which maintain health in the healthy—are, in fact, all contained in the word "sanitation," if we include in it genuine cleanliness of person, domicile, air, water, and foods.

The remarkable fall in the death-rate from all tuberculous diseases, but more especially from the pulmonary form which has taken place during the last thirty years, although I grant it has not received a full explanation, can scarcely have been uninfluenced by the widespread improvement in the sanitation of this country which the same period has witnessed. Without desiring to undervalue the effects in this direction which may have been due to measures which have diminished the number or virulence of infective microbes or the occasions for their gaining admission into the body, which measures must have had some share in the results attained, I am strongly of opinion that the generally improved vigour of the people which has resulted from the better and cleaner and more airy houses, with better food and more of it, has had a larger share in bringing about this result. Be that as it may, no one can doubt that our efforts in the future should be directed to the attainment of both objects—that is to say, to diminishing the number and virulence of the bacilli and the occasions for their infecting us as well as to the increase of the resisting powers of the people and, as it were, to the establishment of a more widespread immunity against the tubercle bacillus. That most people are now immune wholly or partially to the attacks of tubercle bacillus I feel reasonably sure, for seeing the ignorance that prevails still as to the infectiveness of the sputa and the prevalence of filthy habits in the public streets, seeing also the vast numbers of medical men and nurses and other attendants upon the phthisical sick who never suffer and also the very large proportion of married people who do not become infected by such intimacy, I think no one can doubt that almost every adult person has at least once in his life received into his breathing organs some of the bacilli and yet only a minority suffer. Also we must remember that although many have been so infected yet they have always resisted the bacilli with success, although in some instances there may have been a struggle to be undergone, such persons being as it were only imperfectly immune, as are, for example, vaccinated persons who have small-pox in the modified form. It is to the production of a more widespread immunity in the future that I look forward with greater hope than I can do to the complete eradication of the bacilli while heartily approving continued efforts in that direction also. To obtain this much-desired immunity I am convinced that the bolder, even the seemingly reckless, mode of life which cultivates hardihood as regards air and temperatures, &c., exerts all the faculties, and maintains the frame with ample foods, is more successful than the old coddling methods which under the euphemism "taking care" cultivated delicacy and made immunity difficult or impossible. If anyone doubts that such immunity does now exist let him consider that it is admitted on all sides that a state of susceptibility exists in some persons and that immunity for others is a natural correlative of this susceptibility and that the facts on which the belief of its existence rests are even more numerous and obvious.

I have not attempted to deal with the other possible, even probable, explanations of the reduction of the death-rate from pulmonary tuberculosis in recent years which, however important they may be as factors, are not so much under our control. I do not, however, doubt that some influence on our death-rate is now being exerted by the deaths in the past of the more susceptible people who were then the unfit. It behoves us now both in regard to private habits and usages and to public regulations to do what may be possible so to train up our children that they may not suffer the fate of the unfit. It will be said with no little force that I have been too optimistic in looking forward to the production by more perfect sanitation of such a large measure of immunity. However, after half a century of experience in practice I am not discouraged overmuch, for I see progress if slow. There remain, however, many giants to be slain and among them one against which I have before tried to do battle—viz., the fear of "catching cold" whenever the ventilation which is needful for perfect health is approached. This one, however, has been logically vanquished by the practice adopted in many sanatoria, for it will not, I think, be possible to maintain that currents of air which do good to a phthisical person do harm to a healthy one.

I am, Sirs, yours faithfully,

Nottingham, Nov. 28th, 1898. W. H. RANSOM.

To the Editors of THE LANCET.

SIRS,—Many of us, no doubt, have been seriously considering the proposals to establish in all parts of England open sheds for the residence of consumptives while undergoing the "open-air treatment." Probably many practitioners, though fully convinced of the great importance to health of a good supply of fresh air night and day, feel some

Digitized by Google

doubt whether during the winter part of the year in our climate the system proposed will be found advantageous in many cases or at all stages of the disease.

Having been accustomed from early youth to be out in all weathers I have enjoyed for some years past the advantages of a large shed or verandah open to the west and south, but well protected towards the north and east, and have often wondered why so few houses in the country are provided with verandahs having glass roofs and large enough to be used as an extra room. Mine is about 36 ft. by 15 ft. The back is formed by the house wall, and the north end and the roof are glazed. It is entered from the short staircase of the cottage. The floor is of wood and is partly covered by carpet. There is ample space for tables, chairs, and other furniture. The soil around and in the neighbourhood consists of sand, peat, and gravel. Fir trees, rhododendrons, and other evergreen trees and shrubs abound and grow freely. An extensive fir wood surrounds three sides of the small wild garden and at the back is an open common. It would probably be difficult to find within easy distance of a large city a place more suitable for outdoor living as proposed, and I have often thought that if unfortunately my air-cells were invaded by a tubercle bacillus I would move my bed into the protected corner of my open-air apartment. In moderate weather it would no doubt be advantageous to do so, and perhaps it would be pleasant. But to attempt this all the year round would be to most of us, however healthy and strong and accustomed to fresh air in all weathers, anything but comfortable. Now this is the fourth day of rain and storm and morning and afternoon mist and fog. To spend even two or three hours and take one's breakfast and dinner in such a place in such weather would be very depressing and would make some people quite wretched. Even the most philosophic and placid of mankind would soon long to warm himself before a good roaring fire. To live under conditions so dreary week after week would, I should think, except to the very strong and thoroughly robust, be almost unendurable. Think of the turning out and dressing and breakfasting in the cold wet fog, and of the going to bed in the dismal drizzle, or when a cold wind was blowing hard. Surely the lot of the soldier exposed to the worst weather and all the hardships of an arduous campaign in winter would be preferable.

In advising a course of action supposed to be to the advantage of the bodily health ought we not also to think of the probable effect of the suggested treatment upon the patient's mind? For although many phthisical persons are hopeful and sanguine and often in good spirits even when seriously ill, I fear life in the contemplated sheds in many parts of England in such weather as we have lately enjoyed would not be happy. If the plan is to be acted upon here, it is to be hoped that only highly favoured localities, where there is natural protection from the north and east winds and where the shed may catch every possible ray of the sun at this time of the year, will be chosen. But under very exceptional advantages it would probably soon be found that something much more lasting and far more costly than sheds and shelters would have to be provided in the vicinity, for some of the cases placed under the open-air treatment.

I am, Sirs, yours faithfully,

Nov. 26th, 1898. LIONEL S. BEALE.

To the Editors of THE LANCET.

SIRS,—Staff Surgeon A. G. P. Gipps in an interesting letter in THE LANCET of Nov. 26th called attention to the danger of investing capital in providing homes for phthisical patients (or perhaps a better name is "kurhaus," the term I noticed used in the beautiful Austrian Tyrol) because our climate lacks the dry air and sunshine of Davos, Falkenstein and so on. If you will permit me I would like to point out that these defects which are grave and serious ones are capable of remedy to a great extent so that those who cannot leave England for these far-off places may still enjoy a climate in some respects better. Twenty years ago I read with interest that if you cannot afford to go to the Riviera then you should bring the Riviera to your own home by building glass houses. This I tried about twelve years since, building a large glass house opening from my drawing-room by a French window. The cost, with a saddle boiler which heated drawing-room and greenhouse, also the aviary if desired was £100, It has always acted well, providing any climate we wished, protected from rain, fog, wind, cold, and providing means for exercise and recreation for my children, friends, and visitors, &c, in a pure atmosphere at all times. I had better state that I live in Sherwood Forest on the new red sandstone at a height of 200 ft. above sea-level and the glass-house is glazed with rolled plate-glass excepting where we wish to look out; this affords a sufficient shade from the sun in summer without blinds or limewash, &c. The floor is of Minton tiles and waterproof. Not only have we a splendid climate, but if we wished we could make it pay its own cost by growing roses and other flowers, so that we could provide occupation, amusement, and recreation, in which our English watering-places are so very deficient.

One point I have forgotten—want of sun in winter, which is a great evil; but on our east coast, especially in such places as St. Andrews, Deeside, and Bridlington Quay there is a great deal of sunshine—that is, of course, because the rainfall and clouds are less; but there is another point. The electric light has proved useful in the growing of flowers and might serve to produce light in place of sunlight, though whether it would be as health-giving would require to be proved. The cost of an oil engine producing about forty lights of twenty and thirty average candle-power is £200 and then the cost of maintenance is equivalent to the cost of the same light by paraffin lamps, so that really the outlay would be £200 with cost of renewal of machinery when worn out.

I am, Sirs, yours faithfully,

Dec. 5th, 1898. M.O.H.

INTUSSUSCEPTION TREATED BY LAPAROTOMY.

To the Editors of THE LANCET.

SIRS,—May I add the notes of another case of intussusception to the series that appeared in THE LANCET of Nov. 12th, 1898?

On August 13th, 1898, a female infant, five months old, was admitted to the Leeds Infirmary, with a history of pain in the abdomen, vomiting, and of passing blood-stained motions and some mucus. The child had only been ill for four days. On admission a sausage-shaped swelling could be felt in the region of the cæcum and extending across the abdomen. On the afternoon of admission ether was administered and an incision about 2½ in. long was made in the middle line of the abdomen. On passing the hand into the abdomen an intussusception was felt and that part of the bowel was brought outside the abdomen. The intussuscepted part was found to be ileum into cæcum and ascending colon. The intussusception was easily reduced and was then returned within the abdomen. The abdominal wound was closed. The patient was discharged on Sept. 6th well.

I am, Sirs, yours faithfully,

W. H. BROWN,

Dec. 5th. Surgeon to the General Infirmary at Leeds.

"OBSERVATIONS ON AN INFECTIOUS DISEASE IN LASCARS HAVING CLOSE RELATIONS WITH VARIOLA AND VARICELLA."

To the Editors of THE LANCET.

SIRS,—We have read with great interest the letter in THE LANCET of Nov. 19th by Dr. Izett Anderson in which he refers to our paper on the above subject. His letter is of special importance as corroborating in certain respects some of our impressions of the disease referred to, as its comparatively slight infectivity, unless among communities closely confined, as on board ship or in penitentiaries. The fact that none of the patients who came under the care of Dr. Izett Anderson died likewise agrees with our own experience, though this was necessarily limited. It is obvious when we take this latter point into consideration that the disease is not to be regarded as of importance except in so far as it may be mistaken for variola, and we question whether it would not be an exceedingly difficult matter to recognise sporadic cases of this disease in a community in which small-pox is more or less endemic. In the outbreak recorded by Dr. Anderson as well as in that observed by ourselves the cases were very favourably placed for observation in so far as they were seen at a time when small-pox was absent, with which therefore they could not be confused. In a community where small-pox and this

Digitized by Google

disease coexist it is clear that a certain amount of difficulty must present itself regarding the relation of the two diseases to vaccination. In Dr. Izett Anderson's letter it is stated that the disease occurred "in old and young, vaccinated as well as unvaccinated, and also in some who had had severe attacks and were deeply pitted by antecedent small-pox." Our own experience was precisely the same as this, but in addition, as stated in our paper, the patients were susceptible to vaccination during the course of the attack and were not protected from the disease by antecedent successful revaccination, while two unvaccinated individuals who mixed freely with the diseased lascars were not affected.

This unusual behaviour towards vaccination is entirely contrary to our experience of small-pox, as observed in Britain, and at once suggests the possibility of the existence of two diseases closely resembling each other in their more important clinical features but entirely different in their cause and in their influence on man. As stated in our paper we have invariably failed to vaccinate successfully persons who have just passed through an attack of small-pox, while the number of successfully revaccinated persons contracting small-pox is so small that out of upwards of "14,800 cases received into hospital [Metropolitan Asylums Board report] only 4 well-authenticated cases were treated in which revaccination had been properly performed." This corresponds with our own experience in Glasgow.

In addition to these considerations the differentiation of the disease from small-pox is suggested by various official reports which have appeared from time to time concerning India and other Eastern countries. The anomalous behaviour of vaccination and inoculation so frequently mentioned in these reports may be explained by assuming that many of the so-called inoculations have been performed with lymph derived, not from cases of true small-pox, but from patients suffering from the disease we are now discussing. In the Army Commission Report,[1] 1879–80, for the Central Provinces of India it is stated that in Sambulpur town, when small-pox broke out at that time, "it attacked those who had been inoculated, vaccinated, and had previously had small-pox....301 persons who had been inoculated took the disease out of a total of 1607 cases." This is so glaringly contrary to the generally accepted opinion with regard to the protective efficiency of inoculation that comment is needless.

In the sixth report of the Royal Commission on Vaccination, Appendix 15. Art. Japan, Table IV., is a report on the Tokio small-pox epidemic of 1891–92, in which 5215 cases of small-pox were observed, of whom 260 are stated to have had small-pox before. Of these, 80, or about 30 per cent., died. Here both the proportion of second attacks and the death-rate are so striking as to suggest either that the information derived from the patients regarding a previous attack of small-pox was erroneous or that the first attack of so-called small-pox was not small-pox at all but a disease resembling it in its clinical features though differing from it in respect of its protective influence against variola. Examples of this kind might readily be multiplied.

In conclusion, we would suggest that statistics with regard to the relationship between small-pox and vaccination, which indicate so marked a discrepancy from the opinion generally held, demand a most careful investigation by those who are in a position from their experience of small-pox in the east to carry on the work inaugurated by the publication of Dr. Izett Anderson's paper in 1867.

We are, Sirs, yours faithfully,
R. S. THOMSON, M.D. Glasg.
JOHN BROWNLEE, M.D. Glasg.

City of Glasgow Small-pox Hospital, Nov. 28th, 1898.

[1] Vaccination Commission Minority Report, par. 227.

DIPHTHERIA ANTITOXIN.

To the Editors of THE LANCET.

SIRS,—Having recently read before the Hunterian Society a paper which dealt amongst other things with the effect of the antitoxin treatment on the fatality of diphtheria in London I have perused with much interest Dr. Cobbett's paper which appeared in the last issue of your journal. With respect to London he has come to exactly the same conclusion as that to which I arrived when he states that "the new remedy has been more readily adopted by the hospital physicians than by general practitioners." Fig. 1 in Dr. Cobbett's paper shows that whereas formerly the fatality of cases of diphtheria admitted to the Metropolitan Asylums Board's hospitals was considerably higher than that of all the cases occurring in London (that is to say, for both those cases admitted to hospital and those not admitted), since 1894 the difference has been lessening and in 1897 the fatality of admitted cases was slightly less than the fatality of all the cases. But I think that Dr. Cobbett understates the case. Comparing the figures given in Table 3 of his paper with the figures given in the reports of the Statistical Committee of the Asylums Board I gather that (by "admissions" Dr. Cobbett means the admissions when corrected for errors of diagnosis and not the number of notified cases admitted. A considerable number of cases, for the most part mild in character, are not reckoned amongst the diphtheria admissions at all, and the figures Dr. Cobbett gives do not include these cases. On account of this correction it has always been impossible to accurately compare the fatality of the admitted cases with those not admitted, for it may be safely assumed that a considerable proportion of the latter are not cases of diphtheria. Hence curves B and C in Fig. 1 of Dr. Cobbett's paper cannot be accurately compared one with the other. It seems to me, however, that a more accurate comparison can be made. We know exactly the annual number of deaths from diphtheria in and outside the Asylums Board's hospitals. We also know exactly the yearly number of notifications. We can also obtain accurately enough the number of notified cases admitted to the Asylums Board's hospitals. In the Statistical Committee's report for 1897 the actual number of these cases for that year is given, but for previous years the percentage alone is stated, from which the number admitted can be calculated. From these data we can calculate the fatality of notified cases admitted and of notified cases not admitted and we can then compare the two rates. In my paper I drew up a table showing these rates since 1892 as follows:—

—	1892.	1893.	1894.	1895.	1896.	1897.
Fatality per cent. of all notified cases	23·8	24·6	24·7	21·2	19·4	17·4
Fatality per cent. of all notified cases admitted to M.A.B. hospitals	24·8	27·1	25·0	18·3	17·7	14·9
Fatality per cent. of all notified cases not admitted to M.A.B. hospitals	21·5	23·7	24·5	23·3	21·3	20·1
Percentage of notified cases admitted to M.A.B. hospitals	30·1	24·5	38·8	41·5	39·9	51·4

This table shows, but more emphatically than Dr. Cobbett's tables, that whereas the fatality of hospital-treated cases was up to 1894 greater than that for the whole of London, since that year the reverse has been the case. It also shows that the improvement in the fatality rate is more marked in the hospital cases than in those not admitted to hospital. It further shows that there has been some improvement in the fatality of the cases not admitted, a fact also pointed out by Dr. Cobbett. It is very uncertain that the improvement in these last cases is due to the use of antitoxin. Doubtless some cases are admitted to the general hospitals and are treated in them with serum. Possibly the improvement may be due to that fact, but if so it only emphasises Dr. Cobbett's statement quoted above to the effect that outside hospitals the antitoxin is little employed. I have no doubt myself that this statement is perfectly true. My experience at the Eastern Fever Hospital, where there have been for eighteen months past about 200 beds set aside for diphtheria, leads one to say most emphatically that in the East-end of London, at any rate, the employment of antitoxin in the treatment of diphtheria is the exception. It is very rarely that a patient is admitted who has been treated with antitoxin before admission, even when he has been ill for several days. And from what I know personally of the action of the remedy I have no hesitation in saying that there are hundreds of children who die every year in London for want of its timely employment. I say "timely" because although of recent years the Asylums Board have been admitting a large proportion of the notified cases, yet the proportion of cases admitted at an early stage of the disease seems to be diminishing.

I must apologise for the length of this letter, but the subject is important. We have a remedy for a very fatal

Digitized by Google

disease which by consent of the majority of those medical men of all countries who are best qualified to pronounce an opinion is of the greatest value in the treatment of that disease. Yet of this disease the children of the poor are still allowed to die in their hundreds annually in this wealthy city of London, largely for want of the remedy. Why this should be is worthy of the most careful inquiry. Dr. Cobbett is to be thanked for drawing attention to the fact.

I am, Sirs, yours faithfully,

Homerton, Dec. 4th, 1898. E. W. GOODALL.

AN ENTERPRISING AGENT.

To the Editors of THE LANCET.

SIRS,—I have sent a copy of a printed letter to each of the practitioners here and am sending one now to each at Tewkesbury, Upton-on-Severn, Bromyard, Ledbury, and Kempsey, which contains the following passages:—

> Two practitioners here have informed me that the following offer has been made to them by a man representing himself as an agent of an insurance office. In return for placing the practitioner's name on a card as medical officer the agent would use his influence to obtain patients for such medical officer, offering 1*d.* per week for each male or female adult, and ½*d.* for each child, without any wage limit or other restriction. This offer has been absolutely declined. I send this circular to you that you may learn what has been done and confidently suggest that no self-respecting member of our profession would accept such terms.

Had the terms offered been accepted it would have followed that the practices of neighbouring practitioners would have been exploited for the good of the medical officer. I hope you will be able to expose such a nefarious scheme in the pages of THE LANCET.

I am, Sirs, yours faithfully,

St. Michael's, Malvern, Dec. 6th, 1898. STANLEY HAYNES.

*** We do not know that further exposure is required from us. Readers of THE LANCET know that this is a method of tactics which has been adopted by certain medical aid associations. We commend Dr. Haynes's prompt action. After receiving the circular letter no medical practitioner in the neighbourhood can accept the enterprising agent's proposals without knowing that he is defying the opinion of his professional brethren.—ED. L.

BRITISH MEDICAL BENEVOLENT FUND.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if you will kindly insert this appeal in your columns. For many years I have received and distributed articles of clothing for men, women, and children and am now practically without. I should be glad to have anything that can be spared, such as hats, jackets, dresses, or underclothing for women, or blankets, boots and shoes, old furs, overcoats, or anything, in fact, that has some wear in it and likely to be useful.—I am, Sirs, yours faithfully,

16, Upper Berkeley-street, W., Dec. 3rd, 1898. EDWARD EAST.

"THE CONSCIENTIOUS OBJECTOR."

To the Editors of THE LANCET.

SIRS,—I do not agree with Dr. Woodward's remarks on vaccination certificates in THE LANCET of Dec. 3rd.

Though strongly opposed myself to this new Act—one of the most mischievous, I think, which the present Government has passed—still I do not consider it is right for our profession to suggest to magistrates a series of questions which will make it even more difficult than it is now for conscientious applicants to obtain their certificates.

The very fact of many such applicants being so often willing to lose half a day's work plus the fee for certificate when they could have their children vaccinated entirely free of any expense should tend, I think, to make one believe in the earnestness of their convictions and so shield them from being unnecessarily heckled. Much as I should rejoice to see this Act repealed, yet so long as it is in force magistrates have only to administer the law (which was evidently meant to bear a liberal construction) without allowing their private opinions in any way to bias their judgments to the detriment of the petitioner.

I am, Sirs, yours faithfully,

Dec. 3rd, 1898. J.P., F R.C.P.

AN ACADEMIC GOWN FOR THE MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—I much regret that through the lateness of the hour my somewhat hurried sentences prevented clearness of expression and that you failed to grasp my reasons for the utility of a distinctive academic garment for the operating surgeon. I certainly did not say or do I think that a "flowing robe" would be desirable *per contra;* I said "*not* in the flowing gown of the learned Roman nor exactly in the surplice of the clergyman," but I thought some suitable white washable garb for the operating surgeon was both desirable and *needful* and would be a great improvement to the somewhat gruesome appearance of many of our operating surgeons in their private practice. I have seen very hideous coverings worn by operating surgeons and the "mackintosh apron" you speak of is quite the exception. One surgeon I know used to wear his old worn-out dressing-gown for hospital operations. A proper recognised operating costume would, too, be not only cleanly but of hygienic value. For State occasions some different and more scholastic gown would be appropriate, I opine, for I believe I have read of the toga prætexta with its purple border, the toga virilis, the toga picta of the classic Roman, sometimes embroidered with gold, and I think there was nothing unseemly in my suggestion that the Fellow should have a purple hem or some other distinction from the ordinary Member denoting his special rank. Better thus than that the line of demarcation should still further be widened and that the Fellow should be given collegiate dress to the *exclusion* of the more numerous and scarcely less worthy and intelligent Members.

The time will doubtless come when every physician or surgeon will as a matter of routine don his gown and his academic sash will be on his table when in his consulting-room. The utility of this will be even to you, Sirs, probably obvious, although you may not have felt, as I have felt, the inconvenience or experienced the unfriendly gaze of your patient who has consulted you when you have been clad in boating or cricket costume, to saying nothing of the hunting field or the familiar suit of the cyclist or even of our plain evening dress. These frivolities are not *contra bonos mores* or against professional skill and diligence; yet who has not at times felt he would have been glad to have hastily covered these signs of avoiding or trying to avoid dull care or gloomy thoughts by hastily donning the academic robe and assuming at once the naturally thoughtful expression and sagacious countenance of the successful and friendly medico which will so fittingly become the scholarly *rôle* of your future surgeon?

I am, Sirs, yours faithfully,

THE SECONDER OF THE RESOLUTION FOR THE ACADEMIC GOWN OF THE M.R.C.S.

Dec. 5th, 1898.

THE SICK AND WOUNDED AT OMDURMAN

To the Editors of THE LANCET.

SIRS,—As the medical officer in charge of one of the barges which left Omdurman on the morning of Sept. 4th and on which the wounded received attention from the 2nd, will you allow me to answer the letter of Major-General Russell which appears in the *Times* of to-day, and I will take the statements he puts forward *seriatim*. Firstly, the wounded were not packed like sardines but had ample space, the mere fact that the angarebes or native beds on which they were lying measured in some instances more than 3 ft. across making it an impossibility to accommodate more than a limited number on the deck. Secondly, native beds were at hand, and were in excess of the requirements, and were used in every case on my barge where I considered them necessary. Thirdly, the operations performed by myself and my junior officer (amounting in all to 12) whilst on the way down the river were performed on a special operating-table which I had with my field hospital during the entire march and subsequent action, and which was thought by us to be of so good a pattern that it was used subsequently for every operation that was performed at the Abadia Hospital. Fourthly, my operating space on the barge was in the stern and it was carefully screened off and enclosed on both sides

Digitized by Google

and ends from observation, and patients were as comfortable in it as in a building and not a single operation was undertaken "on irregular piles of ammunition boxes" for two reasons—firstly, because we had an excellent operating table and, secondly, because there were no ammunition boxes on the barge. Fifthly, the chloroform was not blown away and, as we were working under the upper deck, the "piercing rays of a burning sun," described by the correspondent of the *British Medical Journal*, would have had to penetrate 4 in. of planking which made up the floor of the upper deck and the roof of the barge above this. In conclusion, I must state no operations, with the exception of a very urgent one, were performed on the barges until Sept. 3rd, on which date plenty of native beds were obtainable.—I am, Sirs, yours faithfully,

MEDICAL OFFICER IN CHARGE OF
Dec. 5th, 1898. NO. 1 FIELD HOSPITAL.

THE EPIDEMIC OF TYPHOID FEVER AT BELFAST.

SECOND YEAR.

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 1437.)

THOUGH both the private drains and the public sewers of Belfast are most defective and the subsoil is extensively contaminated there are still persons who persist in maintaining that the real fault lies with the water-supply. Personally I have been blamed for not going to inspect the catchment grounds and for not emphasising the risk that the water-supply incurred of being specifically contaminated. Nevertheless, in my report published in THE LANCET of Nov. 27th, 1897, I mentioned that a list of 16 farmhouses had been given to Dr. Frankland, who was then investigating the question of water-supply, where the drainage from stables, manure heaps, houses, &c., discharges either into the subsoil or the adjoining small water-courses which are all situated on the Stoneyford gathering ground supplying Belfast with drinking-water. Further, I added: "At the commencement of the year there were four cases of typhoid fever in one of these farmhouses, and it is urged that it was only after these four cases on the gathering ground that the fever became so general in Belfast." Such, briefly, was the contention brought forth last year and it was met by the fact that typhoid fever was endemic in Belfast and that the deaths from typhoid fever were much less numerous during the first than during the last three-quarters of the year. If the epidemic had been caused by contamination of the water at the date mentioned it should have occurred during the first three months of the year and should have been much more widespread. As a matter of fact it was just when the water was supposed to be contaminated that there were the fewest number of deaths from typhoid fever—namely, 58 deaths up to April 3rd, 1897. During the second quarter of the year there were 100 deaths, 81 deaths during the third quarter, and 97 during the fourth quarter. At the farm in question the cases occurred in February, 1897, and they were described as gastric fever. It was not till the following October or November that water samples were taken from the little brooklet into which this farm is likely to drain. The water taken above the farm was not so pure as that taken below the farm.

But all these details are of little or no importance. They mainly serve to divert the population from the chief points at issue. It is admitted, it must be admitted, the Water Commissioners themselves do not attempt to deny that contamination of the water catchment may occur. Where there are farms and manure this is inevitable; and at any moment cases of typhoid fever may take place among the farmers who live on the catchment area. How often have typhoid dejecta reached the Thames from the 1,250,000 people who live above the water intake of the London supply? The safety of the people of Belfast depends not on the condition of the catchment but on the filtration of their water-supply. As a rule this filtration removes from 97 to 98 per cent. of all the bacteria which the water contains. This, the result of Dr. Frankland's analyses, is confirmed by those of the Local Government Board analyst, Professor Hodges, and by Mr. Barclay, teacher of chemistry, analytical chemist, and member of the Belfast Corporation, therefore it may be considered very satisfactory. As for the catchment area it was selected at a time when the rapid growth of Belfast was not fully foreseen, and the farms have sprung up since that time. As a consequence, and at a cost of £610,000, new gathering grounds have been secured in the Mourne Mountains and works are now proceeding to bring this new supply down to Belfast. For this purpose a conduit 38 miles in length will have to be built and no one disputes the purity of the new supply. This vast undertaking was fully described last year, but it will require some time to carry out. In the interval the best must be made of existing circumstances. The position differs from that which prevails in England and it has its advantages and disadvantages. In England farms generally vary from 100 to 300 acres in size and have but one house. In Ireland they vary from 10 to 40 acres and each farm has its house. The Irish farmers are poorer and more dirty. Consequently they are individually more dangerous to the water-supply. On the other hand, these small farms are generally taken for grazing purposes—they are not tilled and manured as in England. But it is very difficult to move these small farmers. They farm according to tradition and are quite impervious to all claims of modern city life. They pay their rent and place their manure heap where most convenient to themselves. Belfast and its water-supply is no concern of theirs. The Water Commissioners have even tried to purchase some of these farms, but the farmers will not sell. Recently the former spent £30 in laying drain-pipes so that the water from a farm might be diverted from one of the town-supply conduits and made to pass under it. There are certainly legal powers which might be employed, but it is necessary to prove that there is pollution, and at present the sanitary officers do not seem willing to swear that a privy situated at a distance of 500 yards from a water reservoir is a nuisance. The Water Commissioners recently caused a concrete tank to be installed in the place of an ordinary privy at a school which was situated about a mile away from the Leathemtown reservoir. This hesitation seems to indicate weakness on the part of the sanitary authorities. The law should be strong enough to suppress all leaking privies, whether there be a water-supply conduit near to them or not. The precautions ought not to be taken only by the Water Commissioners. For instance, at the present moment the main gravitation conduit from the Woodbourn supply is being dug up and altered for a distance of three-quarters of a mile as it passes through the Antrim-road district. This conduit was completed in 1868 and is made of brick and cement. Now as this neighbourhood is being opened out for building purposes iron pipes are substituted for the brick conduit. On the other hand, any sewers or drains passing across the easement of the water conduit must be made of water-tight metal pipes laid under the supervision of the Water Commissioners. This is good so far as it goes, but no sewer should leak, whatever may be the material with which it is made and wherever it may be placed. Two years ago two-thirds of a mile of iron piping was substituted for the brick and cement water conduit which passed near to the Throne Hospital. The fear was then entertained that the water might get contaminated, but this cuts both ways, for if it shows lack of confidence in the water conduits it also indicates that the drainage was likely to be unreliable. It may, however, also be said that brick conduits cannot stand the heavy traction of a growing city, and big, heavy carts are less likely to break iron pipes. Of course, as the town extends the underground conduits must be of iron.

Having regard to all the circumstances Belfast seems to be in quite as favourable a position with respect to its water-supply as most towns and in a better one than many, and in 1901 a new and much better supply will be available. Then, as mentioned before, a water epidemic would produce a far greater number of cases occurring in a briefer space of time. Nor is Belfast the only place afflicted with typhoid epidemics when there is every reason to believe that the water-supply is not contaminated. Sir Charles A. Cameron, medical officer of health of the political capital of Ireland, at the recent Public Health Congress, insisted that the Dublin water-supply was of exceptional purity, yet with the exception of Belfast no town in Ireland had a higher death-rate from typhoid fever. Typhoid fever prevailed in Dublin because the subsoil was contaminated by

Digitized by Google

leaking sewers, drains, and cesspools. As these were removed public health improved, but the micro-organisms of this disease could retain their vitality in the soil long after the cause of pollution had ceased. Sir Charles A. Cameron added that the "connexion between enteric fever and the soil is shown by the results of observations of the distribution of more then 4000 cases of the disease in Dublin. Where gravel forms the site of the streets there is far more typhoid fever than in the districts which rest upon the stiff boulder clay. This is clearly owing to the fact that the bacillus typhosus, which is aerobic—that is, requires oxygen—can get it more freely in the loose gravel than in the stiff clays. In the gravel, too, there is much greater space for the development and movement of the bacilli."

When Mr. Dunlop, speaking on behalf of a deputation opposed to sanitary reform, urged upon the Belfast Town Council that he owned many houses with privy closets where no case of typhoid fever had occurred, he forgot to mention that they were, for the most part, built on clay soil. The real problem for Belfast to solve is the purification of the subsoil in those extensive portions of the town where it is composed of sand or of rubbish. These are traversed by streams which have become sewers and sewers which have become cesspools. Then there are house drains which leak and privies which are not watertight. As Dr. Brouardel said of Toulon, the home of typhoid fever and of cholera, so may it be said of Belfast, "the town stands on a fæcal soil." Councillor Dr. O'Connell expressed at the Town Council his opinion that the Blackstaff stream, as it passes through Belfast, received the drainage from some 10,000 people and he thought that most of the sewers in the town would have to be relaid. There were heavy deposits in these sewers and till this state of affairs was rectified the typhoid fever epidemic would recur over and over again, especially after prolonged dry weather.

To remedy these most unsanitary conditions it is proposed to obtain special powers from Parliament so as to impose the water-closet system on all houses, to test all existing domestic drains, and to introduce back passages where these do not exist. This sounds well, but how are the water-closets to be drained. If they are to be led into the existing drains the second condition may become worse than the first. At present many houses drain into a private drain which passes through the back yards and only joins the public sewer where the row of houses is cut by a street running at right angles; thus a private drain behind the houses of a street running from north to south will fall into the public sewer of the first street it meets running from east to west. If there is a stoppage in this private drain the drainage from all the houses above the stoppage will be blocked. This is bad enough where, as at present, in houses with privies this private drain only receives the rain water, the scourings of the back yard, and the slop water, but it would be worse still if these drains also received the contents of water-closets. Again, as these are private drains, they must be repaired by the house-owners and are consequently very generally neglected. Rack-renters and speculators in poor property cannot be trusted to keep such drains in order. It stands to reason that these private drains should be converted into public sewers and placed under the supervision of the public authorities. Where at present there are two private drains running parallel in the yards of two rows of houses which stand back to back they should be replaced by one public sewer draining the houses from both sides. Where there is no back passage 2 ft. of space should be taken off the yards on either side. This would make a passage 4 ft. wide, under which a proper public sewer might be laid which could be constantly inspected by the sanitary authority and repaired at once when any accident occurred. As it is, if the private drain is out of order it may remain in that condition for weeks and months before the mischief is discovered and legal proceedings are successfully taken against the landlord. This back passage would also serve for the removal of the contents of the dust bins. If, however, the back yards are so small that there is absolutely no room for cutting a passage through them the whole property should be condemned and pulled down. Nor would this be an extravagant proceeding. On the contrary, a good deal of money could be made out of the transaction, for the houses which come under this catagory are of such a wretched description that it would pay to build in their stead a better class of property. This would have the further advantage of improving the appearance of the town—a phase of reform which, from the æsthetic point, is as urgently needed as is a better sanitation from the public health point of view. To demand power for the compulsory enforcement of the water-closet system without first securing powers to construct proper public sewers would be to place the cart before the horse. The private drains which exist are not fit for such a purpose nor can they be controlled with sufficient promptitude by the sanitary authorities.

Councillor Miller has made a proposal on these lines to the Public Health Committee; and, further, he explained to me that it might be worked financially in such a manner as in a great measure to cover the cost of some compensation to the owners. Councillor Miller calculates that the expenditure would be something like £7 10*s.* per house, of which sum the house-owners should pay £5 and the town £2 10*s.*; or, in all, about £50,000. But under the present conditions the cleaning of the privies, &c., costs the town about £4700 per annum. The borrowing of £50,000 would cost in interest and amortisation some £3400 a year, so that an economy of about £1000 a year might be realised. But there are strong objections made to the giving of any compensation to the owners. Certainly if the actual owners were alone guilty of creating the present unsanitary state of affairs they ought not only to be made to pay the entire cost but they would also merit some form of punishment. Unfortunately a great part of this bad property is now owned, not by those who built the unsanitary dwellings, but by innocent purchasers. The ratepayers of Belfast so far neglected their duty as to elect officials who sanctioned the erection of buildings which would obviously become unfit for habitation. The present owners in many cases trusted the town council and claim to be the victims of incompetency. The result is a high death-rate and permanency of typhoid fever in Belfast. If to rectify matters the purchaser must sacrifice 2 ft. of space in his backyard and pay £5, may not the ratepayer be called upon to pay £2 10*s.* as an atonement for his share in the bringing about of the present disastrous conditions? The elected were to blame—they sanctioned what they ought never to have allowed; but why did the electors vote as they did?

The Bill to be presented to Parliament as it now stands is vague. After numerous details about tramway lines and miscellaneous matters comes the following short clause: "To confer powers on the corporation to require the owners or occupiers of houses to provide water-closets and from time to time to lend to such persons money to assist them in this object." And in another clause: "To divert, alter, and remove sewers, drains, tubes, wires, pipes, and apparatus," as may be necessary in connexion with the various proposed works. This may be a sufficient description of what is supposed to be intended; but should not this be accompanied by a detailed plan? It is all very well to build water-closets, but where and how are these closets going to be drained? Surely not in the ineffective private drains which exist. And where are public sewers to be placed for those houses which have no back passages? Then the actual main sewers are not big enough to carry off the water when it rains heavily. Floods are of constant occurrence. What will be the condition of the public sewers when some 20,000 additional water-closets drain into them? If floods are to bring back the contents of the closets and deposit them on the floors of the houses the fewer closets which communicate with such sewers the better. Not that the present privy system is to be maintained for a day longer than necessary, for the flood waters also reach the privies, lift their contents, and carry them into the houses. But is it not evident that the Bill should comprise a scheme for the modification of main and branch sewers of the town?

(To be continued.)

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Pasteur Institute for Hyderabad.—The Plague Commission.—The Progress of the Epidemic.—The Native Chiefs' Health Institute.

THE following details have been published concerning the Pasteur Institute at Hyderabad. It is expected that His Highness the Nizam will lay the foundation-stone of the new laboratories next week. The idea of a properly-equipped Pasteur Institute for Hyderabad was originally conceived and

Digitized by Google

is now taken in hand by Colonel E. Lawrie, I.M.S. It has been supposed that such an institute can only be worked satisfactorily in the cool climate of the hills, but it appears to the Nizam's Government that it will be more satisfactory to work it on the plains under conditions which obtain naturally as regards heat, moisture, and climate generally. The institute will aim solely at being of practical use to the Government and the Medical Department, to the numerous private practitioners in the Deccan, and to the public. It is said that the institute will be provided with the necessary laboratories, well stocked with all the latest scientific appliances, and it will adjoin a hospital which is maintained by the British and Nizam's Government jointly. It will therefore be available for the accommodation of patients of all classes of both Governments alike. The institute is not only meant to afford rapid help to all persons bitten by poisonous animals and thus save them from suspense and loss of time and money, but it is intended that the fullest possible bacteriological, chemical, and pathological investigations shall be undertaken in order to throw light on the common and widely fatal diseases of the climate of India. The educational side of the institute will be one of its principal features. The student of the local medical school will be trained in the most modern methods of observing, treating, and preventing disease, and by degrees all hakims and hospital assistants at present in the service of the Nizam's Government will undergo practical training in all that is necessary in these methods. One of the adjuncts of the institute which has proved of immense value in the recent investigations into the pathology of plague and malaria will be a photographic laboratory. The institute will be superintended by a Hyderabad medical officer who has recently undergone special training in Edinburgh, Paris, and Berlin. The whole scheme is entrusted exclusively to Colonel Lawrie. One cannot but admire the spirit and enterprise which has prompted such a scheme, and if from the above outline it seems somewhat ambitious yet it will doubtless be of great educational benefit. The programme is sufficiently exhaustive to satisfy the greatest enthusiast.

The Government resolution concerning the Plague Commission says: "A number of interesting facts have already been collected and embodied in different reports regarding the outbreak of this disease which has prevailed in India during the past two years, but there must be many valuable items of information to be ascertained from officers who have been employed on plague operations which have not been recorded in official reports, and there are also many circumstances connected with outbreaks in different places which require to be locally examined by persons who can collate facts and form conclusions." This expression of opinion only bears out what I wrote previously—that officers of the Local Government Board accustomed to investigate the outbreaks of infectious diseases are the men who are really wanted. The points for the Commission to investigate are: (*a*) the causes of the different outbreaks and the circumstances influencing their growth and decline; (*b*) the manner in which the disease is communicated; and (*c*) the effects of curative serum and of preventive inoculation.

The Presidency plague returns have not improved. There have been 6223 attacks and 4858 deaths recorded for the past week. In Bombay city there were only 59 deaths but there have been heavier totals in Broach, Thana, Dharwar, Bijapur, Baroda, and Kolhapur. In Dharwar district alone there were 2940 attacks and 2374 deaths.

At Bangalore there has been considerable trouble—riotous disturbances, a strike in the Conservancy department, high prices of food and materials, and concealment of cases. The disease is very rife, 627 cases and 522 deaths having occurred during the past week. From the date when the province of Mysore was first attacked up to the present time there have been 3292 cases and 2555 deaths. The epidemic is spreading in southern India. It has lately broken out in the goldfields of Mysore. Large numbers of coolies have become scared but inoculation is being pushed forward as rapidly as possible.

The Punjab after having been free for some months has suddenly developed a few cases at the town of Rahon in the Jullunder district. This town has a population of 11,000 and has hitherto marvellously escaped notwithstanding that it is situated on the margin of an area which has been infected during the past two years. It is an ancient and decayed town with few means of communication and it would be easy to temporarily suspend intercourse with neighbouring places. A few cases continue to manifest themselves every few days in Karachi city. Calcutta apparently remains free.

The Native Chiefs' Health Institute, the details in connexion with which have not yet been published, will have for its objects (1) the scientific study of bacteriology; (2) researches regarding the causation of disease; (3) the investigation of means for the prevention and cure of disease; and (4) the training of officers in bacteriology and to carry out investigations on the above lines. This seems very much like the programme of the Hyderabad Institute, more especially as it has been reported that the long-looked-for Pasteur Institute for India will be taken in hand and will form part of the Native Chiefs' Health Institute. Provided they are well supported there is doubtless plenty of work for both institutions, but it would be a great pity for the cause of science if one institution marred in any way the success of the other.

Nov. 19th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Sewage Difficulties.

THE Public Works Committee of the City Council have presented a report on the condition of the sewers in the Edgbaston and Harborne districts. In this inquiry it was found that the sewers were in a faulty and in places dilapidated condition necessitating entire reconstruction to ensure efficiency and safety. The area reported on by the city surveyor comprises some 3625 acres with a population of 21,000. The bulk of these sewers were constructed between the years 1863 and 1879, consequently they have been subjected to much wear and are now inconsistent with the more advanced principles of present-day knowledge. Small brick sewers, with the bricks at places perishing, joints most imperfectly made, and the jointing material when used being now decayed, have given rise to accumulations of filth and escape of foul emanations which have resulted in numerous complaints. The problem has therefore to be faced with as little delay as possible. The scheme of the city surveyor has been considered by Mr. Mansergh, C.E., and with some modification adopted. It has been resolved by the city council that the sum of £155,000 be borrowed in accordance with the estimate proposed—a resolution which was passed at a subsequent meeting of ratepayers.

Electric Lighting.

A public meeting of ratepayers of the city was held on Nov. 26th to authorise and empower the corporation to apply to Parliament for an Act to authorise the transfer of the Birmingham Electric Supply Company to the corporation. The Lord Mayor (Mr. Alderman Beale) stated that they had purchased the concern for £420,000, which was at the rate of 10 guineas a share. A clause is added to the Act empowering the corporation to build branch schools of art, to make improvements in the Rubery Hill Asylum, and to pay for music in the parks. Already the gas and water undertakings have been acquired, and as the tendency of the present time is to municipalisation of large concerns for the public benefit there seems to be nothing needed beyond a cheerful acquiescence and the payment of the necessary costs.

Adulteration of Food.

A batch of offenders were recently brought before the magistrates and fined in various amounts for wilful transgressions in the adulteration of food. A butcher for selling diseased meat was fined £5, while a man who had sold diseased fish got off with £2 and costs. Another was fined £9 for selling margarine as pure butter, while a margarine manufacturer trading as the Elbercraize Creamery Company for not having his manufactory registered was fined in all £43 4*s*. It is doubtful whether fining, even in substantial amounts, is the best plan of dealing with fraudulent purveyors of food. A term of imprisonment when such offences are repeated by the same person would be more likely to stamp out this pernicious evil.

St. John Ambulance Association.

The eighteenth annual report states that during the year the accounts show a surplus of £19 6*s*. 7*d*. Twenty classes have been held, but still the association appears to be but poorly supported, the subscriptions received from the members amounting only to £7 12*s*. Three more wheeled

Digitized by Google

litters have been placed at the disposal of the city authorities at a cost of £36 to the local centre. It has been thought desirable that when on duty the members of the Birmingham corps should appear in some official clothing, and the question of uniform will be brought up at the annual meeting. Possibly some enthusiasm will be stimulated by an appropriate uniform.

Dec. 6th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Crematorium Company: Seventh Annual Report of the Council.

THE Liverpool Crematorium Company has now entered on its third year's working. The annual report of the Council states that 23 cremations have taken place during the year ending Sept. 30th, 1898, which compares favourably with 7 in the first year. The working account of the first year showed a loss of £239 4*s.* 2*d.* In the second year the loss has been £70 5*s.* 6*d.* Thus progress is evident, but so slow as to be disappointing and discouraging. Nevertheless, the evidence of belief in the system as manifested by its adoption in unexpected and most varied quarters and by persons of weighty character encourages the committee to recommend perseverance, many signs indicating that adverse sentiment is gradually though slowly yielding. They continue to believe that the maintenance of a well-conducted establishment must eventually lead to the wider adoption of a system against which none but sentimental objections can be brought. At every cremation the operation has been completely successful and the manager and his assistant have now become thoroughly familiar with the work. There is no present occasion to ask for contributions for maintenance on account of the loss on the year. The response to the committee's appeal last year was larger than was necessary to clear off the adverse balance then existing and the debt to the bank is only a little more than £10. The committee again urge the desirability of expending about £400 to complete the columbarium, which for want of funds has been left unfinished. The building, garden, and entire establishment are in perfect and pleasing order. The crematorium is a handsome Gothic structure and is considered to be the finest of its kind in this country. In the opinion of Dr. Hope, the medical officer of health of Liverpool, the crematoria at Milan and other places on the continent which he has visited are not so appropriately constructed as the one at Liverpool.

Proposed Small-pox Hospital at Fazakerley: Powers to Supervise Shippons.

The Port Sanitary and Hospitals Committee of the City Council have recommended the purchase of a site at Fazakerley containing 30,669 square yards for the purpose of erecting 2 pavilions, to contain 22 beds each, for the accommodation of small-pox patients, at a cost of £3500. The ground adjoins a site purchased by the corporation some time ago for hospital purposes. The cost of the pavilions and accessory buildings, including furnishing and drainage, is estimated at £20,000. The City Council, on the recommendation of the Health Committee, are about to apply to Parliament for powers to enable them to make provision for protecting the public against the spread of diseases by the sale within the city of the milk of cows with diseased or indurated udders and for taking samples of milk within the city for the purpose of bacteriological examination; also for the entry of the medical officer of health or a specially authorised inspector into any byres or cowsheds or other places within or beyond the city where cows are kept from which milk is sent for sale within the city; also, to examine the cows therein for the purpose of ascertaining whether such cows suffer from diseased or indurated udders and for preventing the milk of cows so affected being sent for sale within the city.

The new Northern Hospital: Completion of the Nurses' Home.

The Nurses' Home of the David Lewis Northern Hospital has now been completed. The home, which forms part of the scheme of the new hospital, is an imposing structure in red Ruabon brick. There are 3 floors, each with 20 bedrooms and a sitting-room, in addition to 2 smaller sitting-rooms. Each floor is supplied with bathrooms, lavatories, box-rooms, &c. In the basement are other box-rooms, kitchen, scullery, larder, and a room in which lessons will be given to the nurses in cookery for the sick. The building, which is light and lofty, is supplied with excellent heating and ventilating apparatus and the sanitary arrangements are admirable. The furnishing has been carried out in a tasteful manner.

The Liverpool Medical Institution and the Treatment of Tuberculosis.

Dr. T. R. Bradshaw proposed the following resolution at the last ordinary meeting of the above society:—

That a committee be appointed to consider what further steps can be taken for the prevention of tuberculosis in the city of Liverpool and for the treatment of the disease in the human subject.

Dr. Bradshaw suggested some of the subjects with which the committee might deal: (1) the dissemination of sound views as to the nature of phthisis, especially that it is communicable, preventable, and to a large extent curable; (2) the provision on an adequate scale of sanatoria in the country; (3) the more effectual control of the sources of infection; and (4) the desirability of adopting some form of notification. The resolution, in the unavoidable absence of Dr. E. W. Hope (the medical officer of health), was seconded by Dr. E. P. Manby (the assistant medical officer). The members who were selected to serve on the committee are: Dr. W. Macfie Campbell (the president), Dr. E. W. Hope, Dr. Thomas Clarke (chairman of the Hospitals Committee of the City Council), Dr. James Barr, Dr. William Carter, Dr. Caton, Dr. N. Raw, and Dr. T. R. Bradshaw who will act as secretary to the committee.

Annual Dinner of the North-Western Sanitary Inspectors' Association.

Mr. F. Vacher, medical officer of the Cheshire County Council, presided over the eleventh annual dinner of the North-Western and Midland Sanitary Inspectors' Association. The company was large and representative, including medical officers of health of important towns, the Mayors of Birkenhead, Wigan, and Crewe, Professor Boyce of University College, Liverpool, and others. Dr. William Carter, in proposing the toast of the "North-Western Centre," commented on the constitution of the newly formed board for the examination of sanitary inspectors in so far as there were no sanitary inspectors upon the board. He advocated incorporation on the part of the association so as to afford them a better opportunity of improving their position by such reforms as independence of tenure and more adequate remuneration. Mr. William Stansfield (chairman of the centre) and Mr. H. H. Spiers (the honorary secretary) replied. The latter mentioned that there were now 321 members on the roll of the association, being an increase of 72 over last year. The Mayor of Wigan alluded to the reforms which had of late years been effected in sanitary matters in Wigan. He referred more particularly to the destruction of insanitary property and the building of model dwellings. Stress was laid on strengthening the ties between medical officers of health and sanitary inspectors. Mr. T. E. Sampson, the coroner of Liverpool, in proposing "The Visitors" spoke of the marked improvement in the dwellings of the poorer classes in Liverpool, a change which had been greatly brought about by the work of the sanitary inspectors. Dr. Hope, the medical officer of health of Liverpool, remarked that the Liverpool Water Committee in their scheme for water wells were at present appointing qualified sanitary inspectors for the purpose of supervising the quality of the ground upon which their water fell. This was a very important opening for the sanitary inspector.

Presentation to the Ex-Mayor and Mayoress of Bootle.

Dr. J. McMurray, the late mayor of Bootle, was presented by a number of friends with his portrait painted in oils. The picture represents Dr. McMurray attired in academic costume and wearing his chain of office. Mrs. McMurray was at the same time presented with a star of large diamonds and a gold necklace set at intervals with pearls. Alderman Holding, the late Lord Mayor of Liverpool, presided over the proceedings.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The New President of the Royal College of Physicians of Edinburgh.

DR. JAMES ANDREW has been elected President of the Royal College of Physicians of Edinburgh for the ensuing year in succession to Sir John Batty Tuke whose term of office has expired. Dr. Andrew holds several of the minor medical appointments in the city and was formerly a physician to the Royal Hospital for Sick Children. He is a graduate of Edinburgh of 1866 and is actively engaged in general family practice.

The Outbreak of Typhus Fever in Edinburgh.

Since the report which appeared in THE LANCET last week seven additional cases have occurred and have been removed to the City Hospital. I regret to have to say that one of the nurses in attendance on the cases contracted fever and died. She had been for many years in the hospital and I understand was much valued and respected on account of her professional attainments, her high character, and her exemplary bearing.

The Princess Louise at the Queen Victoria Jubilee District Nursing Institution.

Her Royal Highness the Princess Louise visited the Edinburgh Branch of this institution last week and presented badges and medals to some of the nurses. Her Royal Highness always takes a warm and practical interest in the working of this institution.

Glasgow University.

Professor Adamson, LL.D., has been appointed by the Senate an assessor in the University Court for four years in succession to Professor Jack, LL.D., whose term of office has expired. The examinerships in chemistry, zoology, materia medica and therapeutics, and clinical medicine and clinical surgery are advertised as vacant.

"The Hospital Story of Glasgow."

A lecture on the above subject was delivered by Dr. Erskine to the Toynbee House Literary Society. The development of the hospital system was traced from the thirteenth century, at which date a hospital is known to have existed in the Polmadie district. An account of the Leper Hospital established in 1350 on the south of the Clyde was also given, and the lecturer referred to the death of Robert the Bruce as probably due to leprosy. Dr. Erskine further described the origin and progress of various existing institutions and concluded his lecture by urging the claims of the scheme of the Lord Provost for the rebuilding of the Royal Infirmary. A number of interesting maps, drawings, and photographs were exhibited.

Glasgow Victoria Infirmary.

The annual meeting of qualified contributors was held on Dec. 1st, Bailie James Dick in the chair. The report dealt with the progress of the hospital and with the more recent acquisition of a convalescent home. The vote of thanks to the medical and surgical staff was acknowledged by Dr. Alexander Napier, who referred to the value of the position of the hospital as an aid in the treatment of disease.

Faculty of Physicians and Surgeons, Glasgow.

The annual dinner of the Faculty was held on the evening of Dec. 2nd, the president, Dr. H. C. Cameron, being in the chair.—Mr. J. M. Cowan, B.A., M.B., B.C. Cantab., having passed the necessary examinations, has been elected a Fellow of the Faculty.—Mr. Ernest Thomson, M.D. Edin., has been appointed an Examiner in Physiology on the Scottish Conjoint Board.

Presentation to Dr. J. B. Russell.

Dr. J. B. Russell has been the recipient of a further testimonial in the shape of a silver tea service and reading desk presented to him by the staffs of the sanitary department and infectious diseases hospitals. In acknowledging the presentation Dr. Russell gave some amusing details of the difficulties encountered in the early days of the sanitary service and showed how gradually public confidence had been gained by the officials of the health department and hospitals.

Resignation of the Medical Health Officer of Paisley.

It has been known for some months that considerable friction has existed between the Paisley local authority and its medical officer and this has now culminated in the resignation of Dr. Donald. The dispute arose in connexion with an outbreak of enteric fever in the early summer which led Dr. Donald to recommend certain improvements in connexion with the distribution of the water-supply so as to prevent any possibility of contamination from the sewers. These recommendations were not adopted by the local authority. More recently a report on the bacteriological examination of the domestic water-supply has been made by Professor Frankland of Birmingham and though he has not detected the presence of the typhoid bacillus the presence of the colon bacillus was demonstrated in the majority of the samples. Professor Frankland denounces the arrangement condemned by Dr. Donald—the direct connexion of the water mains with the sewers by a valve which is opened for flushing purposes—as "an outrage on the principles of modern hygiene." It is in consequence of the unwarrantable opposition to the sanitary reforms which he has long advocated that Dr. Donald has intimated his determination to resign. The local authority has in the meantime postponed consideration of the question.

Poisoning by Ammonia Gas.

In the current number of the *Glasgow Medical Journal* Dr. T. K. Monro and Dr. Workman report two fatal cases following the inhalation of ammonia gas the result of the bursting of a pipe in connexion with a refrigerating apparatus. In each case the post-mortem examination revealed much congestion of the conjunctivæ and deeper tissues of the eyes, evidences of emphysema of the lungs, the bronchi and their sub-divisions being acutely inflamed and lined with a false membrane. The tongue and parts about the fauces presented a raw inflamed appearance, whilst the gullet was free from evidences of irritation, though some patches of congestion were present at the cardiac end of the stomach. The kidneys were acutely congested and the blood was dark and fluid.

St. Andrews University.

The University Court has issued a draft ordinance for (1) the foundation of a Berry chair of anatomy and (2) the foundation of a chair of physiology. The proposal has produced a somewhat angry discussion in the University Council, but in the end the Council decided to support the action of the Court. This decision is in harmony with the determination to provide at St. Andrews University a complete curriculum in the subjects of the first three years of medical study.

Aberdeen Hospitals.

In consequence of his appointment as gynæcologist at the Royal Infirmary Professor Stephenson (Professor of Midwifery in the University of Aberdeen) has resigned his position as surgeon at the Royal Hospital for Sick Children. The directors have accepted the resignation with regret.—The Town Council have made arrangements for giving on Dec. 20th a Christmas treat at the City Hospital (infectious diseases). There are at present about 170 patients in the hospital.

Extension of the Corporation Baths, Aberdeen.

The new wing at the Corporation Baths at the sea beach was opened this week. It contains a hot-room and Russian bath, with sitting- and lounge-room accommodation, sitz bath, and 12 plunge baths and lavatories. It also contains a boiler-room, with 2 steam-boilers and 4 copper water heaters, in connexion with which there is a chimney-stalk of ornamental brick. Like the rest of the buildings the new wing is composed of red compressed Welsh brick with white facings. The whole establishment was designed by Mr. John Rust, city architect, and Mr. John Ogilvie has acted throughout as inspector for the corporation. Altogether there are twenty-eight plunge baths and the total cost, including that of the large underground swimming pond recently opened, has been up to this date about £10,000. An esplanade is being formed out of the city refuse—to extend from the bath-house northward to the mouth of the River Don—and of this about a mile has already been constructed.

Aberdeen Medico-Chirurgical Society.

This society is now to obtain from the Town Council a disposition of the ground in King-street on which the

Digitized by Google

society's hall, &c., stand. It is curious that although the ground was bought and the price paid in 1817 no title was then or since got. It is whispered that the society are to sell the present premises and move farther west. The late Sir James McGrigor (to whose memory the fine granite obelisk in Marischal College quadrangle was erected) had much to do with the society in its early days.

Dec. 6th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Medical Association.

THE Council of the Irish Medical Association held a meeting at the Royal College of Surgeons in Ireland on Nov. 29th, Sir Thornley Stoker, President of the association, being in the chair. Dr. Smyth of Naas gave an exposition of the grievances connected with the administration of the Irish Poor-law medical service, dividing his statement under the following heads: the mode of appointment, the want of promotion in the service, the issuing of dispensary tickets, the cost of travelling in dispensary districts, leave of absence for vacation, and superannuation. A special committee, which included Sir Thornley Stoker, was formed to consider and prepare a scheme tending towards the improvement of the Poor-law medical service.

Royal College of Surgeons in Ireland.

At the examinations for the Fellowship of the Royal College of Surgeons in Ireland which have just concluded no less than five candidates, including one lady, were admitted as Fellows.

Royal Hospital for Incurables, Dublin.

The Countess Cadogan opened the annual sale of work at the Royal Hospital for Incurables, Donnybrook, Dublin, on Dec. 1st, in the presence of a large number of visitors. Her Excellency was received by the authorities of the hospital and shown a sort of bazaar or fancy mart where a great variety of beautiful and useful articles produced by the patients of the institution were displayed. Her Excellency expressed much admiration for the patients' artistic work, especially the wood carvings.

The National Society for the Prevention of Cruelty to Children, Ireland.

The Registrar-General for Ireland, Dr. Grimshaw, presiding at a meeting in connexion with the National Society for the Prevention of Cruelty to Children, held on Dec. 4th, referred to the large extent to which gambling by means of insurance on the lives of children existed and emphasised the necessity for proper supervision by the authorities of places in which children were kept at nurse.

The Royal Victoria Hospital, Belfast.

At a meeting of the Executive Committee of the Royal Victoria Hospital on Dec. 2nd Mr. W. Henman, F.R.I.B.A., was appointed architect for the new hospital. He is the gentleman who designed the Birmingham Hospital. The balance-sheet presented by the accountants shows that, taking the sums paid or guaranteed to the building and endowment funds (with the outlay up to date), there remain £102,046 6*s.* 1*d.*

The Main Drainage System at Belfast.

A very influential deputation of residents and property owners on the two sides of Belfast Lough appeared before the City Corporation on Dec. 1st to solicit their consideration of some facts concerning the drainage system of Belfast and its deleterious effects upon their comfort, health, and property. They pointed out that before the present main drainage scheme was introduced the shores of the Belfast Lough were comparatively inodorous. Now during the summer months and on to October there is an appalling nauseating stench ever present in the nostrils of those who, unhappily, own property and reside in the vicinity of the Lough, and this stench, the deputation stated, is each year increasing in intensity and extending further down the Lough and is driving visitors and builders from the districts on each side. This disastrous state of affairs the deputation ascribed to the discharge of sewage into Belfast Lough without any attempt at filtration or chemical treatment and to the growth and decomposition by the sun and other factors of a certain class of seaweed which is generated and nourished by this deposit of sewage, and also owing to the tidal currents this sewage cannot be removed. The deputation recommended chemical treatment of the sewage and gave an interesting account of what is being done in this direction in London, Glasgow, Manchester, &c. Finally, the deputation urged the corporation to take immediate steps to abate such an appalling nuisance and preserve the residents of the city and those living upon the shores of the Lough from an inevitable recrudescence of the epidemic of typhoid fever which has so frequently been present in their midst. The Lord Bishop introduced the deputation and Mr. Andrews (chairman of the County Down Railway Company), and Dr. Letts (Professor of Chemistry, Queen's College, Belfast) having spoken the subject was referred to the Improvement and Public Health Committees for consideration.

The Health of Belfast.

At the monthly meeting of the corporation held on Dec. 1st it was reported that between Oct. 16th and Nov. 19th 600 cases of zymotic disease had been notified, 387 of typhoid fever, 98 simple continued fever, 94 scarlet fever, 44 diphtheria, 33 erysipelas, 9 membranous croup, and 2 puerperal fever. There were 118 deaths from zymotic diseases, 75 from phthisis, and 213 from diseases of the respiratory organs. The annual death-rate was 25·9. The number of cases of typhoid fever and the deaths therefrom have materially diminished, and the disease seems to be assuming its normal condition in the city, but, as the medical officer of health states, "it [typhoid fever] is rarely if ever absent from amongst us, and so long as this state of affairs remains a fresh outbreak may at any time occur; every care is being taken as far as possible to prevent this."

The Battle of the Clubs at Cork: the Present Position.

It is now very nearly three years since the battle of the clubs began at Cork and it is interesting to review some of the details of the fight up to date. It will be in the recollection of readers of THE LANCET that there were two grievances which the profession in Cork desired to have rectified. One was the small remuneration paid by the clubs; the other was that owing to the absence of a wage limit numbers of citizens who could well afford to pay ordinary fees joined the clubs and private practice was rapidly approaching the vanishing-point. Accordingly there was a meeting of the profession and it was decided that the medical men holding club appointments should resign and that the seniors of the profession should under no circumstances meet in consultation any medical man who might accept the vacated posts. On this decision being officially communicated to the various clubs nearly all of the latter joined together and determined if possible to defeat the combination of the profession. Advertisements were inserted inviting medical men to take up the appointments and it is regrettable to state that they found 4 members of the profession ready to come to their assistance. One of those had been practising in the city for a very short time and was not known to the majority of the local profession. The 3 others were imported from other districts. Club members filled nearly every post in the local newspaper offices and it is hardly to be wondered at that the editors of those papers espoused the cause of the clubs. The clubs met in solemn conclave and the combination of the medical men was denounced in all the moods and tenses. The newspapers were flooded with correspondence in which vituperation of the medical men was the prevailing note. But the latter calmly pursued the even tenour of their way. The mayor, Alderman Meade, who is also mayor for this year, was anxious to procure a compromise and at his instance a deputation from the profession met a deputation from the clubs. Negotiations proceeded smoothly till the club deputation announced as a *sine quâ non* that the medical men—the errant ones—should be taken into the fold of the local profession. The medical deputation at once replied that such a condition was entirely impossible, but at the urgent request of the mayor they decided on bringing the whole matter under the notice of their professional brethren. Accordingly they did so and the action of the deputation was unanimously and promptly endorsed. The fight was not long in progress when one of the imported men died and, later, another left the city. Meantime two or three of the clubs engaged their former

Digitized by Google

medical officers on the terms fixed by the profession and the membership of others diminished by one-half, whilst many of the well-to-do members owing to the publicity given to their action became ashamed of their position and called in the assistance of the ordinary practitioners of the city. The two club medical officers met each other in consultation but club patients often realised the inconvenience of being unable to procure the advice of other practitioners and these two gentlemen were repeatedly obliged to submit to the indignity of resigning their cases into the hands of members of the local profession. So things went on till last week, when one of the two sent in his resignation of the clubs and announced his intention of leaving the city. The clubs state that his resignation is entirely due to family reasons, but for some time past it was freely stated that he found his position of isolation from his professional brethren very irksome. He was kept eternally on the move and no doubt time taught him what was the experience of the medical men who had resigned the clubs that club practice in Cork means "much cry and little wool." The clubs now are in a painfully perplexed condition. One of the newspapers which had been always a strenuous supporter of the clubs referring to the resignation says: "Like the case of the 'ten little nigger boys' they have dwindled down to one." But no one man can possibly cater for the medical wants of the clubs of Cork, neither can he hold a consultation with himself. All the newspapers have had leading articles holding out the flag of truce and suggesting that now is the time for compromise. Be it so. But only on the terms that a fair day's work is worth a fair day's wage.

Dec. 6th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Tetanus by Intracerebral Injections of Antitetanic Serum.

AT the meeting of the Society of Surgery held on Nov. 15th a discussion was opened upon the treatment of tetanus by intracerebral injections of antitetanic serum, a method of treatment which some two months ago seemed to promise such good results. Statistics brought forward by sundry surgeons, however, gave a most disappointing result. M. François Hue had treated a child, aged eleven years, who developed tetanus after a compound fracture of the forearm. Many injections were made but the child died, although the treatment was commenced immediately on the onset of the tetanic symptoms. M. Quénu had employed the method of MM. Roux and Barrel in 2 cases without success although in 1 case where the tetanic symptoms had only lasted two days the immediate results of the injections were good but the patient succumbed from pneumonia on the third day. M. Lucas Championnière had tried the treatment in 2 cases and had had 2 deaths. In one case of chronic tetanus the patient had recovered after one injection, but it must be remembered that patients do recover from the chronic form of tetanus. One surgeon stated that out of 7 cases he had seen 4 of the patients get well spontaneously. The results obtained by MM. Reclus, Chaput, Richelot, Hartmann, and Nélaton were all equally unsatisfactory. In all cases treated by them with antitetanic serum death supervened. M. Peyrot pointed out the difficulty of differentiating tetanus from cerebro-spinal meningitis and asked whether certain cases of tetanus reported as having been cured were not really cases of meningitis.

Unveiling of the Charcot Monument.

On Sunday morning, Dec. 4th, was unveiled the monument to Charcot on a site in front of the Salpêtrière. There were present M. Leygues (the Minister of Public Instruction), the President of the Academy of Sciences, the Director of the Assistance Publique, the President of the Municipal Council of Paris, the Prefect of the Seine, Dr. Jaccoud (the President of the Academy of Medicine), and Professor Brouardel (the Dean of the Faculty of Medicine and President of the monument committee). Many other scientific notabilities also attended the ceremony as well as the members of Charcot's family, of whom the son, Dr. Jean Charcot, married the granddaughter of Victor Hugo and is at present Professor of Clinical Medicine (*chef de clinique*) at the Faculty. The statue is by Falguières and shows Charcot standing upright with his left hand raised and touching with his right forefinger the head of a patient in front of him. The monument stands just to the left of the great gate leading into the hospital. It is in bronze and on the pedestal, which is perfectly plain, is this simple inscription: "A Charcot. Ses élèves, ses amis.—1898." Orations were delivered by Dr. Brouardel, by the President of the Municipal Council, by Professor Raymond (Charcot's successor at the Salpêtrière), and by Dr. Carnil. Dr. Gombaut, a fellow-worker with Charcot, has received the Legion of Honour.

Medical Qualifications in France and the Position of the Alien Medical Man.

In answer to your request for an explicit account of the position of the foreign medical man or foreign medical student I send you the following statement for the benefit of your readers:—Until quite recently there were two medical degrees in France—the *doctorat en médecine* and the *officiat de santé*. The possession of either of these conferred the right to practise, but there was a difference in the conditions under which this right was exercised. Before a student could begin to study for the *doctorat* he had to have gained the *baccalauréat ès lettres* and the *baccalauréat ès sciences*. After having graduated as a Doctor of Medicine he could practise his profession anywhere in France or in any French colony. For the *officiat de santé* the two *baccalauréats* were unnecessary. The medical studies, however, only differed very slightly, but they were less costly. But the *officier de santé* could only practise in one department, and if he wished to change from one department to another he had to pass another examination. This distinction has been done away with by a regulation passed in November, 1892, and the faculties of medicine no longer receive students for the degree of *officiat de santé*. Those who took this degree prior to 1893 are, however, still allowed to practise. The passing successfully through the course of study for the doctorate of medicine enables the student to take either of two forms of this degree, although there is but one course of study. The student can either take the *diplôme d'état*, giving the right to practise anywhere in France or her colonies, or else the *diplôme d'Université*, which has exactly the same scientific value but does not authorise the holder to practise outside France herself. This last diploma was inaugurated to remove certain abuses of privilege by which foreign students who had finished their studies in France under much easier conditions than natives were accustomed to set up in practice in their adopted country. Formerly it was much easier for a foreigner to practise medicine in France than for a native, for the French students had to break off in their medical studies for three years while going through the prescribed course of military service. The protest to which this state of matters gave rise resulted in a new regulation being made by which foreigners who wished to practise in France were allowed to do so as before under easy conditions, but they were only to receive the *diplôme d'Université*. To gain the *diplôme d'état* they have to submit to the same conditions as natives, that is to say, before commencing their medical studies they must pass for the degree of bachelor (*bachelier d'enseignement secondaire français*), then they have to pass a second examination in physics, chemistry, and natural sciences. This latter examination is a new one and without having passed it no one will in future be able to study medicine. To sum up, a foreigner who wishes to pursue his medical studies in France can choose either of two diplomas. If he desires the *diplôme d'état* giving him the right to practise in France he must undergo the same examinations as a native Frenchman, and before commencing his medical studies must pass the same preliminary examinations, the one for the degree of bachelor (*baccalauréat de l'examen secondaire classique*) and the examination in physics and chemistry. Nothing excuses him from these examinations even though he be the possessor of high degrees in his own country. Not even a doctor in medicine of the first-class English universities can practise in France unless he has passed the above-mentioned examinations. If he wishes to obtain the degree of doctor in medicine merely as an honour without wishing to practise in France he must undergo the same course of study as any other student, but there are certain exceptions. Students of foreign universities who can show testamurs from their university duly translated into French and properly authenticated are excused

Digitized by Google

the preliminary examinations and sometimes even the first of their medical examinations, according to the point at which they have arrived in their studies in their own country. Those who have already graduated as doctors of medicine are let off still more easily. If they produce a copy of their testamur translated into French and duly authenticated they are excused the examination in anatomy, physiology, and histology. In fact, they commence their studies as a French third year's student. Being excused examinations, however, does not mean being excused fees. The expenses of foreigners and Frenchmen are exactly the same, however many examinations the former may be let off even when they only want an honorary degree. The total sum is 1385 francs, of which 760 francs are accounted for by entrance fee for four years' study. 385 francs by seven examinations at 55 francs each, and 240 francs by fees for a thesis.

Dec. 5th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Italian Precautions against Pestis Bubonica.

ON board the Peninsular and Oriental liner *Caledonia* proceeding from Bombay and timed to touch at Naples two cases of pestis bubonica were reported *en route*. The Neapolitan sanitary authorities on being advised to this effect made every arrangement for meeting the infected ship in blue water so as to arrest her course and have her conducted to the island-station of Asinara under escort of a war-vessel. The *Caledonia*, however, gave Naples a wide berth and on leaving Port Said steered direct to London.

Recrudescence of Psittacosis.

In the spring of last year I drew attention to the epidemic of infective pneumonia at Genoa, an outbreak which numbered 14 victims and which was traced by the Municipal Board of Hygiene to parrots kept as domestic pets. Cases of an identical form of pneumonia ascribed to the same source had also occurred in Florence and the Genoese Town Council, acting on the advice of its medical referee, issued a circular prohibiting the keeping of parrots in private houses. Since then there has been no recurrence of the epidemic in that quarter, but the traffic in these domestic pets—a considerable one between South America and the ports of the Mediterranean—continues and, diverted from Genoa by the municipal veto, has found markets farther inland. In the Julian Venetia, in the province of Udine, there has been a serious outbreak of infective pneumonia and in one house in Beano (commune of Rivolto) three inmates fell victims to the disease and two of them are dead. On investigation it was found that under the same roof two parrots harboured as domestic pets had died shortly before from the pulmonary disorder and that they had formed part of a consignment of these birds lately imported from South America. Dr. Rovere of the Sanitary Office on becoming aware of the facts had an inquiry instituted, and the provincial medical officer in his report fully confirmed the identity of the disease with that previously manifested at Genoa and Florence. Rigorous measures were accordingly enforced to prohibit the keeping of parrots by private individuals in the commune. The whole subject acquires a special significance in view of the growing conviction that mankind runs far more risks to health and life from contact with the lower animals than till lately was suspected. The cow as a source of tuberculous disease has long been notorious, but it was only the other day, so to speak, that the rat in pestis bubonica and the mosquito in malaria were discovered to enter so largely into the etiology of these disorders. And now we have proof positive of the parrot's agency in causing at least one form of infective pneumonia. The moral to be deduced from the above-indicated phenomena points to a still wider and deeper recognition of nature-study in the medical man's equipment—confirms, in fact, the Hippocratic doctrine that the study of disease belongs to natural history and drives it home with a relevance and a cogency of which the Father of Medicine never dreamed.

Dec. 3rd.

Obituary.

WILLIAM THOMAS WYATT, M.A., M.D. OXON.

DR. WILLIAM THOMAS WYATT, who died at Worthing on Nov. 7th, 1898, was the only son of Sir William Henry Wyatt, J.P. and D.L., and was born in London in 1854. He was educated at Lancing and at Exeter College, Oxford, graduated B.A. with first-class honours in Natural Science in 1876 and M.A. in 1880, when he also took the M.B. degree and proceeded to the M.D. in 1883. His graduation thesis, which was published, dealt with the Pathology and Treatment of Diabetes, the malady which prematurely caused his own death. He became a Member of the Royal College of Surgeons of England in 1879. His medical education was received at St. Bartholomew's Hospital, where his record as a student and after graduation speaks for itself. He was scholar in Anatomy and Physiology in 1877, first prizeman in 1878, and Kirkes' gold medalist. He also held the posts of house surgeon and house physician at the hospital, after which he started in general practice and for about twelve years conducted a large good-class private practice in Stoke Newington, to one of the well-known charities in which district, the Invalid Asylum for Women, Stamford-hill, he was consulting surgeon. During this period also he was an active member of the Æsculapian Society and one of its earliest and most able presidents. His death is a cause of sorrow to many of the members of that society and will recall a period of its existence fraught in the memory of the survivors with many pleasant recollections of the good work which Dr. Wyatt did for it. Some years ago the malady from which he suffered rendered it inexpedient for him to continue his life of activity and he left London to reside at Worthing, hoping he might there do some consulting work for which his abilities eminently qualified him. His health, however, continued to deteriorate and frustrated this desire. He has left a son, two daughters, and a widow to whose care he, humanly speaking, owed some prolongation of his all too short life.

WILLIAM FREDERICK CLEVELAND, M.D. ST. AND.

DR. CLEVELAND who died very suddenly at his residence in Maida Vale from fatty degeneration of the heart on Nov. 24th was one of the most prominent practitioners in that part of the metropolis. He was a native of Suffolk, having been born at Lowestoft in 1823. His medical education was received at Guy's Hospital and in 1846 he became qualified as M.R.C.S. Eng. and L.S.A. In 1862 he graduated as M.D. at St. Andrews University, and at the time of his death he was president of the St. Andrews Medical Graduates' Association, his membership dating from the establishment of the association in 1867. He gave much time to the work of the Obstetrical Society of London and the Harveian Society of London, the value of his services being indicated by his election to be vice-president of the former and president of the latter society. Dr. Cleveland filled several offices in connexion with the British Medical Association. In 1890 he was elected president of the Metropolitan Counties Branch; he was also president of the Ethical Section when the Association met in London in 1895 and his address on Medical Ethics delivered on that occasion was published in THE LANCET of August 3rd, 1895. Dr. Cleveland had practised in Maida Vale since about 1852 and was very popular both with his patients and his professional colleagues.

THE VACCINATION ACT, 1898.—At the meeting of the Honiton Board of Guardians, held on Nov. 26th, it was unanimously resolved, on the motion of Mr. H. Ford (the vice-chairman), to invite all other boards of guardians to join in a petition to both Houses of Parliament, the Local Government Board, and the County Council urging that the new Vaccination Act should be reconsidered with a view to being repealed without delay. Mr. H. Marker (the chairman), who seconded the resolution, spoke strongly against the Act and urged the guardians individually to do all they could to get people to have their children vaccinated.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, NOV. 30TH.

THE Council met this day, Sir WILLIAM TURNER, President, being in the chair, and proceeded with the business of the session.

The Preliminary Examinations.

Dr. PETTIGREW said he wished to make an explanation with regard to what had taken place yesterday during the debate on the preliminary examinations. He had stated that in the Scottish universities double marks or double values were assigned to Latin, Greek, and mathematics in preference over other subjects and the statement had been challenged. Since making the statement he had telegraphed to the secretary of St. Andrews University asking, "Are double marks given in Latin, Greek, and mathematics in the Scottish universities? if so, quote ordinance;" and had received a reply to the effect that Latin, Greek, and mathematics and also English counted double under Ordinance 57, Section 12.

Dr. MCVAIL said it was perfectly true that a higher value was attached to these subjects than to a modern language. That might be right or it might be wrong, but it did not in the least degree affect the question which had been discussed by the Council. The facts, indeed, went to show that the Scottish Universities held a higher class examination than the other bodies.

Alterations in the Council Buildings.

The following report on this subject by the President and Treasurers was received and adopted, viz.:—

The President and Treasurers have to report that satisfactory plans for the addition of another storey to the Oxford-street building have been prepared and are now laid before the Council. They also report that estimates of cost have been obtained from two good firms of contractors — viz., from Messrs. Higgs and Hill, the builders of the Council chamber, for £2349, and from Messrs. Holloway Brothers for £2350, the difference between the two estimates being only £1. Under these circumstances the President and Treasurers suggest that the contract should be given to Messrs. Higgs and Hill. They also advise the Council to accept with thanks the offer of the English Branch Council to advance the capital required at 3 per cent. to the extent of £3000, if required, seeing that the expense of lighting and furnishing the new rooms has likewise to be met. They believe that the suggested alterations of the premises will satisfactorily supply the requirements of the Council. They wish to add that Mr. Rogers, the Council's tenant at 16, Hanover-square, has stated by letter that he will not raise any objection to the raising of the Council's premises, and accordingly the new work will commence at once and be completed by the next session.

Foreign Practitioners.

On the suggestion of the PRESIDENT the consideration of the amended statement prepared by the Executive Committee as to the position of foreign practitioners in the United Kingdom was postponed until the next session of the Council.

Amended Standing Order.

The following amended Standing Order was adopted on the motion of the PRESIDENT, viz.:—

Where it is reported to, or otherwise brought to the attention of, the President or the General Registrar that a registered medical practitioner has been convicted of a felony, misdemeanour, crime, or offence, the matter shall, under the direction of the President, be referred to the Penal Cases Committee for report to the Council, unless in any special instance the President shall deem it desirable to refer the matter to the consideration of a Branch Council, and the Penal Cases Committee or the Branch Council shall, if in their opinion the nature of the conviction renders such a course necessary, not only report the fact of the conviction to the Council, but also direct that the usual notice or summons be sent to the convicted practitioner under Clause 6 of the Standing Orders.

The New Pharmacopœia.

Dr. LEECH presented the following report, viz.:—

The Pharmacopœia Committee beg leave to report that of the first issue of the British Pharmacopœia of 1898, the distribution of which commenced on May 7th last, 18,500 copies were sold before the end of September. As it seemed certain that the remaining stock would be exhausted before the November session of the Council it was thought desirable to print 1500 additional copies, and this opportunity was taken to insert a short list of corrections of manifest errors and misprints. Up to the present time 20,500 copies have been sold, and as only 1000 copies now remain in stock the committee think it desirable that a further issue of 5000 should be ordered. The Pharmacopœia of 1898 seems to have proved acceptable to the medical profession generally and it has likewise been well received by pharmacists. The committee are of opinion that some of the criticisms of the Pharmacopœia should be investigated and reported on by experts and suggest that arrangements should be made for carrying out such investigations and also for accumulating information for the next publication of a Pharmacopœia. They recommend that Dr. Attfield be asked to report on the criticisms passed on the Pharmacopœia and on the progress of pharmacy and pharmaceutical chemistry during the years 1897 and 1898. They recommend also that the pharmaceutical societies be invited by the Council to coöperate in these inquiries and investigations. These societies might be invited by the Council to appoint representatives to confer with members of the Pharmacopœia Committee and the Pharmacopœia Committee should have the power to appoint experts in pharmacy and pharmaceutical chemistry to report upon matters deemed worthy of investigation. The committee further suggest that Dr. Tirard should be requested to act as reporter to the Pharmacopœia Committee on advances in pharmacology and therapeutics bearing on the Pharmacopœia. Some progress has been made with the Indian and Colonial Addendum. It will be remembered that twenty-eight bodies sent in recommendations and suggestions through the Privy Council relative to new remedies or to changes in descriptions and processes desired for recognition in India and the colonies. Many of the suggestions were adopted in the *British Pharmacopœia* of 1898. Others were dealt with in an appendix. The remainder, connected for the most part with recommendations concerning new drugs, were reserved to be dealt with in connexion with an addendum. The drugs recommended for introduction have been carefully examined and described under the direction of the Pharmacopœia Committee and suggestions have been drawn up with regard to preparations which may be required. It is proposed that these descriptions and suggestions, embodied in a report from the committee, shall be forwarded to the Indian and colonial medical authorities, through the Privy Council, and also to other medical and pharmaceutical experts in India and the colonies, with the view of obtaining further suggestions and criticisms prior to the production of the Indian and Colonial Addendum.

Dr. LEECH, in moving the adoption of the report, spoke of the favourable reception accorded to the new Pharmacopœia. In the first six months after its issue as many copies were sold as were sold in twelve months of the Pharmacopœia of 1885. It had been accepted in Canada as well as in the colony of Natal and in Victoria. Indeed, he might say that the new Pharmacopœia had proved specially acceptable in Australia. In the way of dealing with criticisms and accumulating matter for another Pharmacopœia the committee considered that something more should be done than was done after the issue of the 1885 volume; hence the suggestions now made. They proposed that the Pharmaceutical societies should be asked to coöperate from the first and that the Pharmaceutical Society of Ireland as well as that of Great Britain should be asked to give aid. Further they proposed that instead of proceeding independently the societies and the committee should confer together.

Mr. BRUDENELL CARTER seconded the motion.

The report and the suggestions contained in it were adopted by the Council.

Sitting in Camerâ.

The Council sat *in camerâ* for over three hours discussing various legal questions, assisted by Mr. Muir Mackenzie and Mr. Farrer.

The Programme of Business.

A motion proposed by Mr. HORSLEY and seconded by Mr. BROWN that members of the profession visiting the session of the Council should be furnished with a copy of the daily programme of business was negatived.

The Council then adjourned.

THURSDAY, DEC. 1ST.

The final meeting of the session was held to-day, Sir WILLIAM TURNER being in the chair.

Fraudulent Personation.

The PRESIDENT announced that the following motion, moved by Mr. HORSLEY and seconded by Mr. BROWN, was passed yesterday while the Council sat *in camerâ*—viz.: "That the Executive Committee be instructed to report upon means to secure the identification of registered medical and dental practitioners and to prevent fraudulent personation of such practitioners."

The Preliminary Examinations.

The PRESIDENT said that he had received two telegrams with reference to what took place in the Council in connexion with the mode in which the Scottish universities conducted their preliminary examinations. The first was from Professor Butcher of Edinburgh who was one of the Scottish Universities Commissioners and was as follows: "Question of double marks for English, classics, and mathematics has no relation to preliminary examination but only to award of bursaries which are competitive examinations for university distinctions. Yet in these awards modern languages count far more than in English universities." The other telegram

Digitized by Google

was from Professor Stewart, Clerk of the Senate of the University of Glasgow, and was to this effect, viz.: "Amazed at yesterday's proceedings. Ordinance No. 57 applies to bursaries only and has nothing whatever to do with the joint board or with arts or medical preliminary. In the preliminary examinations there is no such differentiation of marks and each subject has 100 for its maximum. Modern and ancient languages stand on equal footing."

Dr. PETTIGREW said he had made his statement under a misapprehension and desired to withdraw it. The point, however, which he wished to make was that this double marking had the effect of keeping back secondary teaching in Scotland.

Later in the day Dr. PETTIGREW asked leave to make a further explanation. He asked the Council to bear with him because he felt he had not done justice to the subject, the telegrams having taken him by surprise.

The PRESIDENT said that the question could not now be reopened.

Dr. PETTIGREW submitted that what he had to say would come in very well at this stage. This marking no doubt applied only to bursary examinations, but these examinations attracted students to the universities.

The PRESIDENT insisted that the subject must be allowed to drop.

Dr. PETTIGREW resumed his seat, protesting that he ought to be allowed to make an explanation and that it was not fair to suppress it.

The Employment of Unqualified Assistants.

On the motion of Mr. TEALE (chairman) there was received and entered on the minutes the following report from the committee appointed on Nov. 22nd to consider certain communications referring to the employment of unqualified assistants:—

1. The committee have given their careful consideration to a letter from the Lord President of the Privy Council, dated August 4th, 1898, enclosing a complaint from Mr. F. A. Wild, and requesting that it might be dealt with by the Medical Council. Mr. Wild states that he was until recently employed as an unqualified assistant by a registered practitioner and alleges that in consequence of the Council's recent notice he was harshly treated in being dismissed at two days' notice from his employment after a service of sixteen years.

A number of other communications addressed to the Council by persons alleging similar grievances in consequence of the same notice have also been considered by the committee.

These cases appear to be all of the same nature as those dealt with in your committee's report to the Council of last session (Minutes, vol. xxxv., p. 128), and they raise the same points as those which were then replied to under the heading of Question iii. in that report.

In so far as they contain requests that the Council should intervene with the object of procuring the reinstatement or re-employment of such unqualified persons as assistants the answer must obviously be the same as that adopted by the Council last session—namely: "That it is not within the province of the Council to take any steps in this direction."

These and other communications which have come to the notice of the committee make it plain that the evils against which the recent action of the Council was directed were more widespread and deeply rooted than was probably realised either by the profession or the public. The removal of such evils must of necessity involve in some cases the disturbance of old-standing but illegitimate arrangements and a certain amount of temporary difficulty or even hardship to the individuals concerned. But notwithstanding this inevitable consequence the committee are convinced that the paramount duty of the Council in regard to the public in general rendered it urgently necessary that the law should be more strictly enforced.

The committee accordingly recommended that the President be requested to convey to the Lord President of the Privy Council and to the other persons who have addressed the Council on the subject herein dealt with the substance of the foregoing remarks.

2. The committee have had referred to them the following communication from the Gateshead Medical Association:—

Gateshead Medical Association, Cotfield House, Gateshead,
Oct. 19th, 1898.

SIR,—At a meeting on Oct. 4th, 1898, of twenty-two practitioners, members of the above association, which includes every practitioner in this town, the subject of the Council's notice *re* unqualified assistants came up for discussion. So much diversity of opinion was manifested as to the meaning of this notice, and the subject is of such great importance to us, that it was resolved to ask the direct opinion of the Council on the following points.

We would respectfully urge that it will be quite useless to refer us to the notice already mentioned. That document was before us at our meeting, but was of no use in settling the points we now lay before you. We would submit that distinct definitions by the Council of the terms particularly mentioned would not only be of great use to the profession, but are due to us in order that we may carry out the exact intentions of the Council.

1. What is meant by a *bonâ-fide* medical student?
(*a*) Is *any* man who has registered as a student, but has not yet passed his final examination, a *bonâ-fide* student? or, if not,
(*b*) How many years must elapse after registration as a student before a man ceases to be a *bonâ-fide* student?
2. What is exactly meant by proper training and instruction of students when applied to pupilage?
(*a*) How long may a student be a pupil?
(*b*) May he be paid any salary?
(*c*) Would board and lodgings be considered as salary?
(*d*) May a pupil be allowed in any case at all to see a case of sickness in the absence of his principal? or
(*e*) Must he in *all* cases be accompanied by his principal?
(*f*) Can the pupil attend a midwifery case alone? If not, what difference does the Council see between the medical schools which allow students to do so and a medical man in private practice who follows their example as regards his pupil?

These questions, Sir, are not asked in any carping spirit or with any intention of questioning the wisdom of the Council's action. We ask them because we find men honestly anxious to carry out the wishes of the Council with widely differing ideas of the Council's meaning.

One man believes that a pupil must only be allowed to attend a case along with his principal, another thinks that if the principal supervise the case the student may visit alone at the practitioner's discretion. Then, again, we are all at sea as to the exact meaning of "*bonâ-fide* student."

Trusting that the Council will see its way to a definite pronouncement on these points,

I am, Sir,
On behalf of the Gateshead Medical Association,
Yours obediently,
ALFRED COX, M.B., B.S. Durham.

The President of the General Medical Council.

This communication has reference to a portion of the final clause of the Council's notice of Nov. 2nd, 1897 (Minutes, vol. xxxiv., p. 122), which states that the notice does not apply "so as to restrict the proper training and instruction of *bonâ-fide* medical students as pupils ..... under the immediate personal supervision of registered medical practitioners."

It appears to the committee highly inexpedient for the Council to issue formal definitions of the terms used in this clause. These terms are obviously employed in their ordinary and natural sense. The students referred to are such as are honestly pursuing their medical studies with a view to obtaining a qualification in the regular course. The primary purpose of the clause is to facilitate the training and instruction of such students during their pupilage in the practice of medicine, surgery, and midwifery, and so to give effect to the recommendations issued by the Council with reference to the five years' course of medical study (Minutes, vol. xxx., p. 82). One of these recommendations is as follows: "The fifth year should be devoted to clinical work at one or more public hospitals or dispensaries, British or foreign, recognised by any of the medical authorities mentioned in Schedule (A) of the Medical Act, 1858, provided that of this year six months may be passed as a pupil to a registered practitioner possessing such opportunities of imparting practical knowledge as shall be satisfactory to the medical authorities."

The duty of a registered practitioner who, in pursuance of this recommendation, undertakes to train and instruct pupils in the practical parts of their profession is obviously two-fold. By his "immediate personal supervision" he must ensure, on the one hand, that his pupils are properly taught, and, on the other, that the welfare of his patients is in no way prejudiced. Supervision which fails to secure both these ends must be regarded as inadequate and the responsibility for such failure must rest with the registered practitioner.

With regard to the training of pupils in practical midwifery the Council has given a sufficient indication of its meaning in its resolution of June 9th, 1896 (Minutes, vol. xxxiii., p. 79). By this resolution it is laid down that every medical student (other than one who has attended the indoor practice of a lying-in hospital) shall, before admission to his final examination, produce a certificate to the following effect:—

"I hereby certify that.....
has personally attended [ ] cases of labour under my supervision, of which [ ] were conducted by him in my presence. Also that he attended under my supervision the women in question during the puerperal period.

".....
"*Registered Medical Practitioner.*"

The committee are therefore of opinion that enough information has already been given to guide any registered practitioner whose purpose is in good faith to afford proper training to his pupils in connexion with his own practice. To go beyond this, by formulating definitions on such matters as *bona fides* and the nature and extent of the supervision that should be exercised, would serve no good purpose in regard to the interests of sound medical training. On the other hand, definitions of the kind might do harm if they led practitioners to have regard to the letter only and not to the spirit of the Council's declarations. Questions of good faith and the like cannot be settled merely by reference to verbal definitions; and it is impossible so to frame general statements of this nature that they shall be applicable to all cases and circumstances. Each particular case as it comes before the Council must be dealt with on its merits and with due regard to all the evidence adduced.

Mr. TEALE, in moving the adoption of the report, said that the intention of the Council in connexion with this matter was to act justly both to the profession and the public, that it intended these to be laid down rather as general principles than as actual details, and that it would deal with any cases absolutely fairly and on principles of common sense. As he had said before there had been a kind of panic in the profession which had exaggerated the supposed effect of the Council's regulations and he thought if they loyally and carefully studied this report, which reaffirmed perhaps in a little more detail the principles in which the Council wished the profession to practise, no serious harm would come to anyone.

Mr. BRYANT, seconding the report, spoke of it as a remarkably good one and expressed the hope that the profession would accept it in the spirit in which it was offered.

Digitized by Google

Dr. MACALISTER suggested that in the certificate they should insert within the brackets "not less than 20."

The suggestion was adopted and the report thus amended was agreed to by the Council.

New Colonial Medical Ordinance.

On the motion of Sir JOHN BATTY TUKE there was received and entered on the minutes the following report from the Education Committee on the Medical Ordinance, 1898, of the Colony of Trinidad, viz. :—

The Executive Committee has referred the following letter, and the Medical Ordinance, 1898, of the colony of Trinidad, to the Education Committee for consideration and report:—

Downing-street, Nov. 9th, 1898.

SIR,—With reference to your letter No. 2895 of the 5th of December, 1887, I am directed by Mr. Secretary Chamberlain to transmit to you, for the consideration of the General Council of Medical Education and Registration, a copy of the Medical Ordinance, 1898, of the colony of Trinidad, together with a copy of the Colonial Attorney-General's report thereon, and to inform you that he will be much obliged for any observations which your Council may be good enough to offer upon this ordinance, which is understood to be in accordance with the views of the medical profession in Trinidad.

I am, Sir, your obedient servant,

The Registrar of the General Council of Medical Education and Registration. C. P. LUCAS.

The committee has to report that the ordinance has no bearing on medical education; it provides for the regulation of the practice of medicine and surgery, dentistry and midwifery, the compounding and selling of drugs and medicines. Notwithstanding, in compliance with the request of the Executive Committee the Education Committee submits to the Council the following abstract of the ordinance. It provides—

(*a*) For the establishment of a Medical Board consisting of persons of good character holding "any medical diploma or licence in respect of which he may be entitled to be registered as a medical practitioner in Great Britain or Ireland."

(*b*) For the election of a Council, consisting of a president, vice-president, secretary, and treasurer, and three members of the Medical Board, "to which shall be delegated such of their powers and duties as are by this ordinance vested in the board as to the board may seem fit." It is lawful for the board *(inter alia)* to make and pass by-laws "for the good rule and government of the members, and the affairs of the board, for regulating the manner of applying and using the funds of the board, for regulating the appointment of examiners for the licensing of druggists and midwives," and "for the doing of such further matters and things not inconsistent with the provisions of the ordinance, as may be deemed expedient and necessary for carrying the same into effect. And thereby to appoint such fines, not exceeding in any case £5, as they deem necessary for the prevention and suppression of offences against any such by-laws."

(*c*) For the sale of drugs and poisons.

(*d*) That "any person, not being a member of the board, who shall after the passing of this ordinance practise medicine or surgery or perform any surgical operation, or give any medical opinion or advice, or prescribe any medical or surgical treatment within this island, in respect of which he shall demand or receive any fee or gratuity, or any remuneration, profit, or compensation under pretext of services rendered, loss of time, travelling or other expenses, under any pretext whatever," and that any person who shall wilfully and falsely pretend to be, or use any medical or surgical title, or "assumes any other step [? style], title, designation, or description implying that he is qualified to practise medicine, surgery, or midwifery," shall be liable to forfeit for the first offence £20, and in default to be imprisoned with or without hard labour for any term not exceeding three months, and for a second or subsequent offence £50, or imprisonment for not more than six months. A similar provision is made to protect dentists.

(*e*) That the Council shall have authority to grant licences as druggists or midwives to persons of good character and who shall give proofs, by examination, of study and training that they are fit and proper persons to act as druggists and midwives.

The ordinance comprises much that does not appertain to the medical profession.

The ordinance has been passed by the Governor and Legislative Council of Trinidad and Tobago and has been approved of by the Colonial Attorney-General.

The committee recommends the Council to intimate to the Right Honourable the Secretary of State for the Colonies that it fully approves of the provisions of the ordinance in so far as they apply to the good rule and government of the medical profession and of dentists in the colony of Trinidad and the protection of the public from the dangers of unqualified practice.

Sir JOHN BATTY TUKE moved the adoption of the report and of the recommendation contained in it.

Dr. MACALISTER, in seconding the motion, said that this was probably the most stringent medical ordinance or Act enforced in the empire. He could well imagine that many members of that Council at least would be glad of anything half so strong that could be introduced into the United Kingdom and he congratulated the enlightened administrators of Trinidad that they had seen that the protection of the public urgently called for something of this kind.

Mr. BROWN said he trusted that this ordinance might be made the basis of legislation in this country for the amendment of the Medical Acts.

Sir RICHARD THORNE said he hoped it would be noticed—and especially by the promoters of the Midwives Bill—that according to this ordinance licences were only to be given in the case of midwives to persons of good character and who gave proofs by examination of study and training that they were fit and proper persons to act as midwives. This was a precedent of the very greatest importance.

The motion was adopted by the Council.

Instruction on Vaccination.

Sir JOHN BATTY TUKE moved and Dr. MACALISTER seconded the motion that the following report by the Education Committee on the instruction of students in vaccination under the new Vaccination Act be received and entered on the minutes, viz. :—

The following communication from Mr. Teale has been referred to the Education Committee by the President for consideration and report:—

"38, Cookridge-street, Leeds,
"September 23, 1898.

"Dear Mr. Allen,—Mr. Scattergood, dean of our medical department, has just heard that the vaccination stations are likely to be abolished under the new Vaccination Act, and he asks me what will have to be done for the instruction of students in vaccination as required by the Medical Council.

"Have you any knowledge of this question?

"Yours truly,
"T. PRIDGIN TEALE."

The committee has had the advantage of an interview with Sir Richard Thorne, K.C.B., principal medical officer of the Local Government Board, at which the question involved was considered. The committee was informed that arrangements were under consideration by which the difficulties raised by recent legislation might be obviated and that the Council would be informed of their nature as soon as they were matured.

Sir RICHARD THORNE said the Council was probably aware that a certain number of public vaccinators in this country were chosen as teachers of vaccination and that all the licensing bodies had decided that they would only accept for the purposes of their licences a certificate which was received from one of the teachers whom the Local Government Board had appointed. Formerly they used to receive them from all the general practitioners in the country and then it was so perfectly obvious to the Local Government Board that many of these certificates were not worth the paper they were written upon that the Local Government Board were unable to accept these certificates for the purpose of public appointments. The consequence was that registered medical practitioners had, so to speak, to go to school again to learn vaccination. That had necessitated the appointment of stations where this could be done and under the new Vaccination Act these stations were practically abolished except under one special clause where they might be retained in the presence of an epidemic of small-pox or other exceptional circumstance. These stations were maintained almost exclusively at the cost of the rates and having already been abolished the Government felt it would not be right to require boards of guardians to maintain these stations at their cost simply for the purpose of teaching medical students. The consequence was that some other arrangement would have to be made. He need not tell the Council precisely what had been done, but he might say that Mr. Chaplin was fully aware of the responsibility which had been assumed by the Local Government Board now that they had tacitly assented, as to speak, to all the licensing bodies requiring a certificate from one of their teachers and he felt the need for such arrangements as would maintain these stations in a position in which they would be able to given these certificates. He (Sir Richard Thorne) hoped that this would shortly be finally settled and then he believed some communication would be made to the deans of all the medical schools in the country.

The PRESIDENT said that this difficulty in Leeds had also been experienced in Edinburgh; they wanted to know where the men would get the certificates.

Sir RICHARD THORNE said the Bill did not in the slightest degree alter the circumstances of Edinburgh. In Scotland they had a domiciliary system which had been lauded so much that England had been compelled to adopt it.

The PRESIDENT explained that they had 3 or 4 stations in Edinburgh.

Dr. REID said there was one in Aberdeen.

Dr. GLOVER moved as an amendment:—

That it be a representation of the Medical Council to the examining bodies that the Council is concerned to find that the recent alterations in the Vaccination Acts may involve changes in the administration of the Acts unfavourable to proper instruction in vaccination in England and would ask the special attention of the bodies to the adoption of means for meeting this state of matters and especially to the possibility of recognising under proper conditions and restrictions instruction in vaccination by private practitioners.

He said that they all regretted the wholesale breakdown in the arrangements for public vaccination in this country and looked with anxiety to the result of the recent remarkable

Digitized by Google

legislation. One chief hope of the country in the matter was in the private influence of the medical profession. Their own regulations recognised that in his fifth year the student might take instruction from a registered practitioner. If there was one thing which a practitioner might be thought capable of teaching it was how to vaccinate an infant. He did not propose to ask the qualifying bodies to recognise the instruction of every practitioner but only the instruction of those practitioners who could satisfy the bodies that they had the means and material of teaching and who undertook to give such instruction carefully. He might say that in Ireland all dispensary officers were public vaccinators and could give certificates of instruction in vaccination which were recognised by the Royal University of Ireland.

The PRESIDENT said that what Dr. Glover proposed was scarcely an amendment but really an independent motion.

Dr. GLOVER said he was quite willing so to regard it.

The Council agreed to receive the report of the committee and enter it on the minutes.

Dr. GLOVER thereafter moved the adoption of his resolution which he insisted was a most reasonable proposition.

Dr. BRUCE seconded the resolution.

Mr. CARTER appealed to Dr. Glover to defer his resolution to the next session of the Council, saying it would be better to make no change until they knew precisely the arrangements proposed by the Local Government Board. If those arrangements were satisfactory and complete, well and good; if they left any opening for additional certification then would be the time for such a resolution.

Mr. BROWN said that Dr. Glover was doing a good thing in calling attention to this matter and he hoped that under the altered conditions the Local Government Board would see its way to recognise this tuition.

The PRESIDENT said that the point raised was a very important one. He recollected that many years ago when he was Dean of the Faculty of Medicine in the University of Edinburgh it had to be considered because they found that their graduates who were not provided with a certificate which was recognised by the Local Government Board had difficulty with regard to obtaining appointments—Poor-law appointments and so on. The matter was brought up and they passed a regulation under which every candidate must produce a certificate from a vaccine department in a hospital, dispensary, or other public institution recognised by the Local Government Board for instruction in vaccination. That was their rule at the present time. They had in Edinburgh three of these recognised vaccine departments, but of course they took certificates from other vaccine departments.

Dr. REID said it was the same in the University of Aberdeen.

Dr. MACALISTER said that Dr. Glover's resolution, if it was to have any effect whatever, ought to be addressed not to the licensing bodies but to the Local Government Board who had the key of the position. If the Board did not choose to recognise vaccination instruction given by a private practitioner the licensing body could say nothing to it. To ask the licensing bodies to intervene in this respect would only be to ask them to stultify themselves. They must approach the Local Government Board.

Dr. MCVAIL moved the previous question and Mr. CARTER seconded.

The PRESIDENT said that after the previous question had been moved there could be no further discussion.

The previous question was carried by a large majority.

Medical Aid Associations.

Dr. GLOVER presented the following report from the Medical Aid Associations Committee, viz.:—

Third Interim Report of the Medical Aid Associations Committee.

The Medical Aid Associations Committee of the Medical Council have to report that they are still in communication with the representatives of the great friendly societies with reference to evils generally admitted or complained of by the medical profession in connexion with medical aid associations. These gentlemen show a desire to ascertain the views of the medical profession and a strong disposition to entertain proposals made by this committee with a view to mitigate the friction now existing. They have represented to the chairman of the committee that at meetings to be held in the earlier part of 1899 they will submit to their constituents a report on this subject. The committee hope with some confidence that at the next meeting of the General Medical Council they may be able to give a favourable account of their negotiations with these representatives of the friendly societies.

The committee are constantly reminded by correspondents of the evils of existing systems by which medical men are placed at a disadvantage by huge institutions under one or two medical officers; sometimes by insurance and other companies purely commercial in their nature and objects, which destroy the respectability of medical practice by methods of touting and advertisement and by the indiscriminate admission to "benefit" of all classes at a rate of remuneration inconsistent with the welfare of the patients and the self-respect of the medical officers.

Dr. GLOVER, in moving that the report be received and entered on the minutes, said that perhaps members might think the committee were rather slow in bringing matters to a head, but it had been explained to them that at the beginning of the new year the meetings of the friendly societies would be held when the representatives of these societies would consult their colleagues as to the proposals made.

Dr. CHURCH seconded the motion.

Mr. HORSLEY said he could not help thinking that they were inflicting hardship upon the profession by not making up their minds upon this subject. He did not think they had any right to go on from year to year merely issuing interim reports which had no practical value. In this matter they were not concerned with the good friendly societies but with the bad medical aid associations, and so far as he gathered the latter did not attend the conference which had been held. He wished to advert to the condition of this question in Coventry. He was informed that a letter had been written to the Council and it obviously came under this heading and what he would propose in regard to the Coventry matter was that the Medical Aid Associations Committee be invited to take up this communication and report upon it during the next session of the Council.

Dr. BRUCE said that Mr. Horsley had scarcely done justice to the committee. They had fully considered this memorial, and they had resolved to make a report upon it at the proper time. Mr. Horsley appeared also to forget the amount of information the committee gave upon a previous occasion. The committee spent days and days over this question of the disreputable societies and he would point out that if they came to terms with the main and extensive societies the others would be, so to speak, nowhere. If the large friendly societies dealt with the committee in a proper way they all, the other medical aid associations, would have to follow suit. He would appeal to the Council that they should not at this particular moment intervene when the committee saw some hope of the question being settled, and settled, he might say, greatly to the benefit of the profession at large.

The PRESIDENT said he might tell Mr. Horsley that the paper he referred to had already been put into the hands of the chairman of the committee.

Dr. GLOVER said that not only had it been put into his hands, but it had been carefully considered by the committee. He would add that he considered it was of enormous consequence that they should come to an understanding with the friendly societies of England. They were a class by themselves, they represented people whom that Council ought to consider, and he was bound to admit that the leaders of these friendly societies had shown a great desire to understand the real needs of the case.

The PRESIDENT said that he was present at the conference and could confirm what Dr. Glover had said.

The motion was then agreed to.

Proposal for a Sinking Fund.

The next business on the programme was the receipt of a report from the Finance Committee on the establishment of a sinking fund.

Mr. BROWN said that as this was a matter on which there was much difference of opinion it should be delayed till next session.

The PRESIDENT thought that Mr. Bryant, one of the Treasurers of the Council, should be heard on the subject.

Mr. BRYANT said that the proposal in question was brought before the Council last year and was referred to the several Branch Councils for consideration and report. The report he had to present included the original suggestions and the resolutions of each of the three Branch Councils. The report of the English Branch Council was as follows:—

Moved by Mr. BRYANT, seconded by Mr. CARTER:—

"That a sinking fund be established by the General Council to repay to the English Branch Council the sum of £25,000 advanced to the General Council for the purchase of the present freehold and the erection of the building, the annual payment being £215 12s. 6d., and the capital sum returned £25,000 at the end of fifty years."

Amendment moved by Dr. MACALISTER, seconded by Mr. BROWN:—

"That, whilst the English Branch Council has no desire to have its mortgage on the building repaid, it raises no objection to the General

Digitized by Google

Council forming a sinking fund for the purpose of repaying it at the end of a term of years."

The amendment was carried, and being put as a substantive motion was also carried.

The report of the Scottish Branch Council was as follows:—

The branch agreed unanimously to support the formation of a sinking fund for the object in question, but to suspend judgment as to further details of the plan, as it was apparent that these still required some consideration.

Sir WILLIAM GAIRDNER: I find that in this report there is a mistake of mine. The Branch Council was not unanimous, as Dr. BRUCE spoke against the proposal.

Mr. BRYANT: Strike out the word "unanimously."

This was done.

Mr. BRYANT said that the report of the Irish Branch Council was as follows:—

The Irish Branch Council have considered the proposal to establish a sinking fund to the amount of £215 12s. 6d. annually for fifty years for the purpose of paying off the debt due to the English Branch, and they are of opinion that such a proceeding is not needful and would, moreover, seriously embarrass the Irish Branch, on whose limited income the additional payment would prove most oppressive.

Proceeding, Mr. BRYANT said that the suggestion he had made was that a sum should be invested with an insurance company so as to carry out the scheme for the establishment of a sinking fund. It had been pointed out that a lump sum of money might be put into the Bank of England or they might make an annual payment to an insurance company. On inquiry at the Bank of England he was advised that it would probably be better to arrange with some one of the first-class insurance companies both on the ground of cheapness and simplicity. He mentioned in the notice of motion he had given only the Alliance Insurance Company. That was because it was a company that did business in this line and was safe and cheaper than any other of the companies from which he had information. Since this question came up he had put it to himself whether another method might not be possible.

Dr. BRUCE: Does Mr. Bryant adhere to the motion of which he has given notice? or does he propose to make another motion?

Mr. BRYANT: I stand by what is printed but I am going to present an alternative.

The PRESIDENT: One moment. The point is this: your report should be received and entered on the minutes. That should be done first.

Mr. BRYANT: Very good, then I move.

Sir DYCE DUCKWORTH seconded and the motion was agreed to.
